## INDEX TO VOLUME II FOR 1926.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocle, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

## A.

**Abdomen** in labour, review of book on, 483  
**Abdominal crises of pernicious anaemia** (Hamilton Bailey), 554 (O)—Correspondence on, 613  
**Abdominal pregnancy.** See Pregnancy  
**Abdominal surgery, anaesthesia in** (H. Finsterer), 290—(Charles W. Moots), 295—(T. Brandt), 297—(C. Langton Hewer), 298—Discussion, 299  
**Abdominal surgery, cases illustrating** (O. A. Jell), 837  
**Abdominal torsion of omentum.** See Omentum  
**Abdominal wall, haematoma of the** (H. R. Gellert), 12  
**Adduction frame, an extensible,** 737  
**AELI, A. L.: Treatment of carcinoma of the oesophagus,** 889  
**AELI, Professor:** Public health in Germany, 845  
**Aberdeen.** See Scotland  
**Abortifacient, lead as an,** 903  
**Abortion, contagious bovine, and undulant fever,** 353, 810  
**Abortion, criminal, two medical men charged with** (Arthur Stuart Holden and Frederick ...), 1 of both prac-  
... induction of  
... (A. Louise  
... 241—(Frederick  
W. Price), 242—(Robert Henry Cole), 244—(H.  
Harvey Evers), 245—Discussion, 245—Leading  
article, 605  
**Abortions, increase of in Germany,** 46  
**ABRAHAM, Adolph:** Functional albuminuria  
in athletes, 135  
**ABRAHAMSON, Leonard:** Diagnosis of coronary  
thrombosis, 1228—Haematuropythyruria, 1229  
**Abscess, acute retropharyngeal, in childhood**  
(Douglas Guthrie), 1174—Discussion, 1175  
... (A. R. Tweedie  
...)  
The recent  
epidemic of small-pox in France, 126—Stan-  
dardization of organic substances used as  
drugs, 212—Report on alcoholism in France, 263  
—Undesirable immigrants in Marseilles hospi-  
tals, 358—Louis Ernest Denos prize, 669—  
An ultra-virus of tubercle, 1189—The general  
secretary visits Japan for propaganda purposes,  
1206  
**Academy, Royal, of Medicine of Brussels:**  
Nomination of president and vice-presidents,  
1204  
**Academy, Royal, of Medicine in Ireland:** Annual  
meeting, 762—Election of officers, 762—Section  
of Medicine: Diagnosis of coronary thrombo-  
sis, 1228—Serum treatment of scarlet fever,  
1209—Haematuropythyruria, 1229—Chronic  
... urbane  
... —Leading  
article, 1002  
**Accidents, street, in London,** 1139  
**Acetabulum, fracture of the** (Wayland Smith),  
1183  
**Acetonuria and migraine** (Marmaduke Fawkes),  
1176  
**Acetylene-oxygen anaesthesia.** See Anaesthesia  
**ACHARD, Ch.: Troubles des Echanges Nutritifs,**  
rev. 1184—Visit to Japan, 1206  
**ACHELSON, Dr.: Tuberculous pyonephrosis,** 1183  
... 183  
... the  
... 492  
... the  
vaccine therapy in a case of (W. Rossell Judal),  
886  
**ADAM, John George, obituary notice of,** 507—The  
Liverpool Cancer Research Organization, 919  
**ADAMS, A. W.: Treatment of congenital talipes,**  
1053  
**ADAMS, Douglas:** Modern aspects of syphilis, 820

## A Lecture ON THE EPILEPSIES.\*

BY

S. A. KINNIER WILSON, M.D., B.Sc., F.R.C.P.,  
PHYSICIAN FOR OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN SQUARE;  
NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING  
NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

THE condition commonly called epilepsy, a "disease" characterized by fits, is familiar to every practitioner of medicine and to many a passer-by in the street; it has formed the topic of innumerable dissertations through the centuries, and has been claimed as a therapeutic preserve by each successive variety of healer, from the divine to the psycho-analytic. As has been the case with other common nervous ailments, from time to time there has been a kind of spurt in the race for a panacea, followed only too often by a reaction after the effort; and to-day various rival and mutually contradictory methods for dealing with it are being advocated, the efficacy of no one of which can be confidently and constantly relied on.

To obtain that definiteness of treatment which must always be his goal, the physician must know the nature and etiology of the morbid condition with which he is dealing and the mechanism of production of its symptoms. Now it so happens that while the external manifestation of an ordinary epileptic fit is apparent to everyone, its inward or neural genesis and progression offer problems of great difficulty and complexity, on which the outward phenomena at the best throw but an imperfect light; from them we are compelled to infer a mode of physiological activity our theories of which are largely speculative, while the symptoms themselves are essentially so transient that the opportunity for objective study is very often too brief to be adequately seized. Like some other nervous affections, in fact, epilepsy is a condition superficially easy of diagnosis but etiologically and pathogenically obscure, and wide excursions in neurophysiology and experimental neuropathology have to be taken to gather such relatively meagre data as are at our disposal in this connexion. Forestalling for the moment what may subsequently be alluded to more fully, I may now state that even if a psychogenic origin be assumed, or proved, for one or other of the epilepsies, the physiological problem presented by the clinical symptoms of the fit is thereby left entirely untouched. To say that a given fit is psychogenic provides no solution; in the words of Hughlings Jackson, "all psychological explanations of physical inabilities are merely verbal," and, as anyone can see, a fit in the ordinary sense is a physical thing.

I propose in this lecture to discuss some of the general and physiological questions connected with epilepsy. Our first is concerned with nomenclature and definition.

### What is Epilepsy?

In ordinary parlance, as sanctioned by long usage, epilepsy is understood to be a disease the outstanding symptom of which is the occasional fit. One has only to mention this conception to realize forthwith its thoroughly unsatisfactory nature. There are many nervous states

\* The Annual Harveian Lecture delivered before the Harveian Society at London on April 22nd, 1926.

of organic origin in which epileptic fits are a symptom; on the other hand, the conception is vitiated by the admission into the category of epilepsy of conditions characterized by "attacks" of a class quite different from the fit as usually understood, but supposedly "equivalent" to epileptic fits because of their recurrence, transient nature, the patient's subsequent conscious ignorance of what takes place during them, and so on. The epileptic fit is nothing else than a symptom; no such disease as epilepsy exists, or can possibly exist; even by resort to such epithets as "essential" or "idiopathic" epilepsy we in no sense add a term of differentiating quality, since the pathological element constituting the disease-component (whatever it may be) is not thereby expressed. Further, assuming that a person who suffers from fits is the subject of a disease which may as well be called epilepsy as anything else, we are unable to say where such a diseased state begins and ends. As is known to every clinician, an individual may have one fit only in the course of his life, or a few, at the widest intervals, as in the case of a lady who had an epileptic fit at the age of 14, when her period of reproductive activity commenced, and another at 44, when it closed. To dub such cases epileptic in the accepted and always somewhat grave sense is clearly unwarranted, but the nature of the attacks shows that they cannot be called by any other name if the term is to retain any descriptive value. Other individuals exhibit at the outset attacks justifiably regarded by the clinical observer as faints, which subsequently merge by ill recognized degrees into the epileptic category. And it is scarcely necessary to point out that ordinary major-epileptic fits are often for a time the sole discoverable indication that a serious organic diseased cerebral state is developing—vascular, inflammatory, toxic, or neoplastic.

Nor is the problem of delimitation easier in respect of the clinical varieties commonly called Jacksonian or epileptiform, and minor, or *le petit mal*. By objective observation on a single occasion of the outward characters of a series of muscular twitches it is practically impossible in many instances to say if they belong to the category of incipient Jacksonian epilepsy, or are rightly described as myoclonus or paramyoclonus, or as tic; additional data not concerned with the extrinsic features of the muscular contractions are often requisite for an exact diagnosis. Most of us have in recent years become familiar with curious varieties of tonico-clonic "involuntary" movements as a sequel to epidemic encephalitis which some Continental observers are already describing as "striatal epilepsy," as though (vain hope!) the solution of their pathogenesis were thereby facilitated; and many practitioners must know of cases classed by them as *petit mal* in which they have never been sure whether the clinical appearances really justified that terminology.

The truth is, as it seems to me, that we have been content to classify fits by certain extrinsic characters or qualities mainly because of our relative ignorance of the intrinsic features of the disorder of neural function which exteriorizes itself as a fit.

### What Constitutes a Fit?

When we come to examine the connotation of the word "fit" we find ourselves in no less a quandary than in regard to the term "epilepsy," for in the ordinary acceptance of that useful expression it stands for conditions as

widely separable as a convulsive movement limited to a segment, or part of a segment, of a limb, or to a part of the face, and highly elaborate co-ordinated acts of the whole person, sometimes of considerable duration, comprised under the term "hysterical fit." The word cannot even be restricted to phenomena of a hyperkinetic class, for it might legitimately be employed to designate certain attacks of which motionlessness is the prominent feature. In other words, "fit" and "convulsion" are not synonymous, and the expression "convulsive fit" is not tautological.

Since, then, it is used to include attacks which vary enormously in type, degree, and duration, not to mention accompaniments, it might be supposed to have become almost meaningless, yet its appropriateness need not be impaired if adequate restrictions are made, and if we can trace the action of some definite physiological mechanism behind its varied phenomena.

General consent, I imagine, will be given to the view that nerve cells in a state of health store up energy in *potentia* derived from the specific nutritional material they absorb or ingest, and that in functional activity normal movements (the reference is solely to motor nerve cells in this connexion, although of course the view applies to all varieties of cell) are the outcome of liberation of this energy in kinetic form, to the accompaniment of expenditure of cytoplasmic material. Such normal liberation of energy is orderly, moderate, and controllable. We can, however, readily imagine a condition of motor nerve cells brought about by abnormal nutrition, and resulting in the development of a state of high tension and instability, whereby they will discharge suddenly, with an excessive liberation of energy, either when a postulated maximum of disequilibrium has been attained, or when a sufficient stimulus reaches them.

Following the profound discussion of this matter by Hughlings Jackson<sup>1</sup> in his Lumsdane Lectures of 1890, I believe that the essence of a fit with convulsive movement consists in the exaggeration of a normal physiological process—that is to say, in the sudden, excessive, and yet purely temporary liberation of kinetic energy in a series of motor nerve cells, the visible consequence of which is a sudden and excessive development of many movements at once. On this hypothesis it is clearly possible for any constellation of nerve cells in the nervous system to become highly unstable or overcharged, and to discharge accordingly, so that the term "epileptic fit" might be employed, and legitimately so, for any paroxysmal symptoms attributable to the process outlined above. Nevertheless, at this point clinical expediency steps in, to warn us not to extend the meaning of the term unduly, even if only theoretically. Avoiding, therefore, too inclusive a conception of the word, we are at the same time arbitrarily limiting its designation when we confine "fit" to a hyperfunctioning of motor cells. The clinical characters, on the other hand, of suddenness, disorderliness, "caricaturing," and excessiveness are cardinal features resulting from the physiological process, and without these no symptoms can be justifiably regarded as belonging to the category in its strict sense. This contention will of itself serve to exclude a considerable number of "involuntary" nervous movements which are the sequel to release of neural function. None the less, as already indicated, it is often far from easy to draw clear distinctions between minor types of "involuntary" movement, especially if the characters just mentioned are not conspicuously present.

#### *The Process of Discharge in a Fit.*

Our next question concerns the determination of the discharge, and its radiation or spread. If we take an epileptiform or Jacksonian fit, we must concede that the focus of pathologically altered cells may be very small. For example, a patient may suffer from Jacksonian fits which always commence by twitching of the same thumb and forefinger; between the attacks he may be perfectly able to move that thumb and finger "voluntarily," hence there can be no material structural defect of the corresponding cortical motor nerve cells. Some pathological condition, however, in the immediate vicinity leads at intervals to such alteration in their cellular nutrition that

they become unstable and prone to discharge "involuntarily" once the adequate provocation arises. As already hinted, we can only speculate as to what this stimulus is, but three possibilities suggest themselves: (1) it may be afferent or sensory, setting off the charge as the detonator fires the powder of the cartridge; (2) it may be intracellular, as though there were "spontaneous combustion" when a maximum of tension and instability is reached; (3) it may consist in removal of some inhibitory factor normally restraining the cell from activity. If this third possibility is entertained the problem is merely put a step further back, for we do not know what neutralizes the hypothetical inhibition and leads to decontrol.

Once the "discharging lesion," as Jackson termed it, is in action, the tendency is in the great majority of cases for its effects at once to spread to neighbouring linked physiological groups of nerve cells, so that in the course of a very brief space of time collateral cells are in discharging activity. It is in no sense likely—indeed, it is hardly possible—that these are anything else than healthy and normal, hence the important conclusion is reached that very little of a Jacksonian fit is directly due to the discharge of abnormally nourished neural units, and that by far the greater part of it is produced by consecutive discharges of normal stable cells. If this be granted, the radiation of an epileptiform fit is entirely a physiological phenomenon, and offers proof of the fact (for which there is abundant evidence otherwise) that healthy neural mechanisms may become epileptogenous, without being in the remotest degree diseased.

In the case of the general, or major, epileptic fit the circumstances cannot be materially different. While on occasion a local commencement (turning of head and eyes to one side) is indicative of the cell groups first implicated in the liberation of energy, in many instances universalization of the convulsion is almost immediate, and the fit is said to be severe. The supposition here is that the initial discharge is particularly sudden and powerful, and that many series of bilaterally situated cell groups have become unstable and, as it were, explosive. With a great quantity of this explosive material radiation through various neural levels evidently occurs with extreme rapidity, and Jackson's words contain no exaggeration:

"speaking figuratively . . . there is the mad endeavour of the highest centres to develop the maximum of function of every part of the body . . . and of all parts at once; the phenomena of a very severe epileptic fit show that this endeavour is nearly successful; the patient is almost killed by the paroxysm, and is nearly dead (deeply comatose) after it."

#### *The Neural Site of a General Fit.*

It is of interest from the standpoint of neurophysiology to determine if possible the neural site of a general epileptic seizure, a question closely connected with the further matter of the type of movements in a fit. This latter subject is examined later, and is to be considered in association with what is now stated.

If we agree that the property of excessive and uncontrolled discharge is common to all cell groups on occasion, whatever their neural situation, it follows as a corollary that at any of the physiological levels of the nervous system epileptic phenomena may make their appearance. Owing, however, to the intimate physiological integration of these levels the symptoms can scarcely be confined to one only unless the initial "discharging lesion" is mild in degree and incapable of overcoming such resistance as collateral groups offer to excitation. Thus, as already indicated, in the case of a severe fit the chief feature is the rapid spread of the excitations through various levels and to differing mechanisms. It is probably thought generally, or is at least a tacit assumption, that ordinary major fits are the outcome of discharges of cortical nerve cells throughout the middle physiological level of both hemispheres (the Rolandic motor cortex)—as far, that is to say, as the visible movements of trunk and limbs are concerned. The view held by Hughlings Jackson was that general epileptic seizures begin in the frontal lobes (his "highest level"), whence the underlying process spreads to and implicates the middle level. Whether this is so or not is extremely difficult to decide; no constant symptom referable to release, or stimulation, of function of the

## THE EPILEPSIES.

JULY 3, 1926]

frontal lobes can be confidently diagnosed; indeed, unless we accept turning of the head and eyes as a frontal symptom (which experimental evidence suggests it may be), no other positive symptom of an ordinary epileptic seizure can be said to have a frontal localization by itself, certainly not the loss of consciousness. It is true that various clinical and pathological data may be taken to indicate (as was discussed at some length in my Croonian Lectures<sup>1</sup>) that a large part of the brain in front of the precentral gyri subserves motor functions; but any motor phenomena its excitation might conceivably produce (with the exception of the not constant head and eyes movement already alluded to) are possibly at once submerged by the spread of the physiological process to the middle level centres. (This point is also referred to below under the heading of "Type of Movement.")

As far as the familiar motor area of the Rolandic cortex is concerned, from the physiological standpoint it is electrically excitable, and from the anatomical it contains the Betz cells, which are the origins of the pyramidal or cortico-spinal tracts running to the ventral horn motor cells of the spinal cord. These cortico-spinal paths are the chief available routes for cortically initiated movements, and exteriorize themselves via the spino-muscular units, and in the case of the movements of Jacksonian epilepsy this is definitely the kinetic route taken. When, therefore, the limbs and trunk are convulsed in a severe fit, the idea is that simultaneous powerful discharge of whole groups of motor cells in the bilateral Rolandic areas is taking place, the result being at first an absolute contention of movement, resulting in relative muscular rigidity—tetanic contractions strictly comparable to that obtained by faradic stimulation of a cortical motor point as long as the stimulus is kept up.

The question arises, however, whether the motor phenomena of a general epileptic fit may not be produced at other levels than the cortical. I have already said that a "discharging lesion," if of sufficient intensity, will rapidly confine itself to one physiological level, but will rapidly implicate others; hence discharges may conceivably be taking place, in this instance, at the spinal level. It is recognized, further, that epileptic fits can be produced experimentally in decerebrate animals in which the brain stem has been transected and (in *addition*) the cortical motor areas and pyramidal tracts put completely out of action. When only the pons, medulla, and cord are experimentally left, fits are still producible, and convulsions may in these circumstances develop *sub finem* just as the respiratory centres are failing. Of course, they are possible only because the spino-muscular units are still living, to be convulsed, but the anatomical paths from medulla to ventral horn cells, traversed by the excitations, are not with certainty known. So far as I am aware, strictly spinal epilepsy—that is, in the purely spinal animal—has not been found experimentally, though there is no theoretical impossibility of its occurrence. In view of these facts and others which are germane but cannot here be detailed, it has been several times suggested, in recent years, that the phenomena under discussion are the result not so much of excitation spreading from higher to lower levels as of removal of inhibition from higher to lower levels, and that the symptoms of the seizure—that is, the motor symptoms—are produced by release of controlling centres; that the epileptic process inhibits controlling centres (say, cortical centres), and that "lower" centres are "let go." Hughlings Jackson himself fully realized this possibility; in his Lumleian Lectures<sup>1</sup> he referred to various "inhibition hypotheses," on which, however, he expressed no decided opinion. It is clear, I think, however, that he was so convinced of the far greater complexity of movement representation in the cerebral cortex that he could not accept the possibility of discharges at low levels being comparable to those of high levels; in his own words:

"it would be marvellous if excessive discharges beginning in centres lowest in rank produced fits like those . . . which are produced by excessive discharges beginning in parts of the more evolved centres, the middle motor cerebral centres. . . ."

The problem is one calling for contemplation from every angle, otherwise we are in danger of reaching a rash conclusion through neglect of the complexity of the

factors. Due attention should be given to the following considerations.

1. While it is agreed that fits of a general kind can be produced in the decerebrate animal, Cobb and Ujemas<sup>2</sup> have shown that a much larger dose of a convulsive agent (absinthe, thujone) is required to cause a convulsion in an intact animal, in which the cortex is active, and they conclude that the cortical motor cells are those most easily and readily stimulated by these convulsants. Pike and Elsberg<sup>3</sup> also admit the greater susceptibility of the uninjured cortex to experimental absinthe fits, although their investigations demonstrated the possibility of the occurrence of both tonic and clonic convulsions in animals deprived of both motor cortical areas, provided an interval sufficient for the return of "good locomotor reactions" was allowed to elapse after the initial operation. These fits "did not differ essentially from absinthe convulsions that occur in unoperated animals"; and, according to Cobb and Macdonald,<sup>4</sup> "the march of events during a convulsion produced by thujone is very similar to that seen during an epileptic fit." Data of this kind, valuable as they must be acknowledged to be, do little more than substantiate the view already outlined, that in appropriate circumstances healthy neural mechanisms below the level of the cortex may become epileptogenic; they certainly do not validate the conclusion that the neural origin of the major convulsions in intact man cannot be cortical. The motor display of major fits is undoubtedly accomplished through spino-muscular units, but more evidence is requisite before the contention can be sustained that the convulsions of organic cerebral disease are, as it were, allowed to occur by removal of some cortico-spinal inhibition.

2. The evidence associating the phenomena of Jacksonian epilepsy with local cortical disease is sufficiently satisfying to dispel any doubt as to their interrelation; that the "march" of such fits is in strict accordance with the accepted physiological localization of face, trunk, and limb centres in the cortical motor area, while no representation of an identical kind has been determined in respect of spinal motor centres, is of fundamental significance. Thus I have twice seen Jacksonian fits involving simultaneously the forefinger and thumb, and the corner of the mouth, on the same side, a combination readily explained by the juxtaposition of the corresponding cortical centres, but meaningless and inexplicable were the epileptogenic site at any lower physiological level.

3. Assuming, for the sake of argument, that the phenomena of epilepsy belong to the category of release phenomena, and that cortical disease only removes cortico-spinal inhibition, we are faced with the problem that the speculation raises as many difficulties as some may think it appears to dispel. We have to explain the violence and the caricaturing element in the motor phenomena—for which are altogether unlike those motor phenomena—example, involuntary flexor spasms—that occur when spinal mechanisms are admittedly liberated from cortical control, as in spastic paraplegia. We have to explain the disorderliness of the epileptic movements, again quite unlike the organized, systematized, scarcely variable movements of released spinal reactions. There is the further difficulty, also, that this postulated temporary release from cortical control is followed by convulsive movements while more permanent release is not.

It seems impossible to avoid the conclusion that there is another element in epileptic discharges than merely a temporary cessation of inhibition from a higher level. We must be careful, indeed, as to our use of the term "inhibition"; transcortical "inhibition" is at least as probable as cortico-spinal inhibition, and the phenomena of epilepsy may conceivably result from decontrol and yet have a cortical site. I have gone more fully into this transcortical question in my Croonian Lectures<sup>2</sup> already mentioned, to which the reader is referred.

4. Perhaps the most significant point is whether, as a physiological fact, lower (say ponto-bulbo-spinal) centres are capable of exhibiting in action as elaborate motor manifestations as are derivable from the cortical motor ganglia, if the expression be allowed. I have already cited Jackson's view that it would be "marvellous" if this were

the case. Unfortunately, this is a matter in regard to which definite observations are unusually meagre and inconclusive. The question is simply this: Are the tonic-clonic convulsions produced by absinthe in the decorticate or decerebrate animal identical in all respects with those readily caused by smaller doses of the convulsant in the intact animal? Only minute observation can settle the point. In respect of man, my clinical experience has led me to maintain that in conditions approximating to physiological decerebration in man the fits that may be met with are essentially tonic in character, and not tonic-clonic, as in intact man. The data supporting this conclusion have been recorded elsewhere.<sup>2</sup> Such evidence as is available, therefore, in respect of diseased states in the human subject does not warrant the speculation that the march of events in epileptic cases is the same whatever the neural level of the discharges; the elaborate sequence of the complicated phenomena of a major attack is not such as can be explained by implication solely of low physiological levels. This brings us to the subject of the type of movements in epileptic fits.

#### *The Type of Movement in a General Fit.*

The ascertainment of the types of movement to be seen in the case of a general fit is a matter of observation, their interpretation matter for discussion. We have to distinguish, also, changes in the motor symptoms during the course of the fit.

Perhaps it is well, in this connexion, to point out that in the fit our concern is with movements and not with muscles. In my Croonian Lectures I have given reasons derived from personal observation for believing that there may be a representation of muscular units in the cerebral motor cortex, but for our present purpose it suffices to say that the motor display is to be regarded as one of movement.

It is most important, also, to realize that "ordinary," co-ordinated movements may and do occur along with and separate from those that are called "convulsed." For example, apart from the latter, the epileptic patient may, during the fit, make champing movements of the jaws, may smack his lips, spit, make clutching movements at the throat; further, when the convulsive phase is over, and while still unconscious, he may make even more elaborate movements of his limbs, such as plucking at his clothes, etc., all of which movements present the characteristic features of purposive, "voluntary," cortical movements, except that they are outside his voluntary control. It is quite impossible to entertain any other conclusion than that these have a cortical site; their complexity and purposive and deliberate character exclude any other explanation.

Convulsive movements proper cannot be considered as anything else than caricatures of normal movements. They are violent, powerful, disorderly, and generalized, and it is not easy to recognize in them either rhyme or reason. Varying considerably in different individual cases, symmetrical or asymmetrical on the two sides of the body, implicating trunk more than limbs or vice versa, or both equally, they represent a maximum of movement in a minimum of time, and no voluntary mimicry can give other than a faint reproduction of their intensity and severity. The arms may be extended fully and hands clenched, or the former may be flexed; the thumb may be inside the clenched hand, or pressed against the forefinger, or the wrist may be powerfully flexed and the hand more open. The legs may move up and down in violent kicking movements, occasionally in crude alternation, but far more commonly in more or less symmetrical and synchronous flexion and extension. From my personal observation and study of very many hundreds of epileptic fits, both general and Jacksonian-becoming-generalized, I cannot satisfy myself either that all epileptic fits, roughly speaking, are alike, or that any definite scheme or organization of movement is revealed in their manifestations. On the contrary, I follow Hughlings Jackson in holding that a convulsion is a "contention of complex, and also of simplest, movements. In this contention the individuality of each movement is lost."

It is customary to speak of a tonic and a clonic phase

of the convulsions. The former precedes the latter in the average general fit; Jacksonian fits are mainly clonic; a special variety occurs (as already mentioned) in clinical conditions corresponding more or less closely to physiological decerebration, and is known as the "tonic fit," since clonic manifestations are not usually an accompaniment.

The tonic stage of a general fit is one of practically universalized immobility; a number of movements, mutually cancelling each other, are developed with remarkable abruptness and equally remarkable power; the result is a rigid state, a "single big useless movement," as Jackson said, followed at length by a succession of such rigid states, a clonic stage, a series of so-called movements "which do nothing but 'mark time.'" Eventually the patient, exhausted by the severity of this contention of movements, which get slower and slower, sinks into a condition, sometimes not a little alarming, of profound collapse and coma, brief though it may be in reality. On at least two occasions I have seen a condition in all its essentials as closely resembling death as I am ever likely to observe.

Holding these views of the physiological phenomena of a general convulsion, I can scarcely regard with patience various speculations indulged in by some, to the effect that the convulsed movements are identical with those of the foetus *in utero*, and that they represent an attempt on the part of the sufferer to retreat again for shelter from an unsympathetic environment into the stillness of the amniotic fluid. I do not consider that they have any "meaning" whatever; they are of no more "significance" than an explosion of powder. Even in respect of the "march" of movement in a Jacksonian fit, the clinical type of exaggerated, caricatured movement in no way resembles those that are called "voluntary" or purposive, while the "march" of the movements follows anatomico-physiological lines alone and presents no point of comparison, but many of contrast, with the co-ordinated movements of a limb in health.

Summarizing at this stage the conclusions reached, largely on clinical grounds, I may state them as follows:

1. The convulsed movements of a general fit resemble those obtained by tetanizing electrical stimulation of the motor cortex (middle level) in their crudeness and severity, and by the action of convulsants on cortically intact experimental animals.
2. In their elaborateness, disorderliness, and violence they do not resemble the involuntary movements known to occur when spinal levels are released by cortico-spinal disease. The reactions of the spinal animal are orderly, systematized, and scarcely variable with variations in the stimuli evoking the reactions.
3. Combinations of movement have frequently been seen in cases of Jacksonian epilepsy which cannot be explained by any known juxtaposition of centres at infracortical levels.
4. Along with the convulsed movements of general fits, "ordinary" movements may occur; these resemble "voluntary" movements, except that the element of "volition" is wanting; their neural site must be cortical, but is certainly not Rolandic. It is therefore conceivable that transcortical decontrol is responsible for some of the discharging movements.
5. As far as man is concerned, fits the origin of which is at some infracortical level are not in all respects identical with those of the ordinary major attack.

#### *The Phenomenon of the Epileptic Aura.*

Consideration of the question of the nature and origin of the epileptic aura is not calculated to lend any support to the view that the manifestations of epilepsy are all essentially infracortical. While not constant (as far as the mind can subsequently recall the initial stages of an attack), it is when present an integral part of the seizure and of localizing value, as every student of the subject is aware. We must keep rigorously in mind the fact that the aura is definable as a sensation, crude or elaborate as the case may be, either referred by the patient to some part of the body or limbs or belonging to one or other of the special senses. Being a sensation, it is a phenomenon of

another order than the convulsive movements; it is a psychical thing, in consciousness, and all that can be said of it physiologically is that we believe it arises during functional activity of some or other central, cortical, sensory mechanism. Because of its being in consciousness its cortical site must be granted (I say nothing here of the speculation that some thalamic activities are accompanied by consciousness of them). In Jackson's clear diction:

"Crude sensations (psychical) and convulsion (physical) are in no way comparable; the comparisons and contrasts are of excessive discharges of sensory elements during which crude sensations arise, with such discharges of motor elements from which convulsion arises."

I do not know that Jackson, who was always conspicuously careful in his choice of words, was justified in claiming the discharge of sensory elements, constituting in consciousness the aura, to be "excessive." On the contrary, it has always appeared to me that, apart from the occasional normal movements accompanying convulsive movements (alluded to above), the aura is the one thing about the epileptic fit which is not disorderly, distorted, or caricatured. Its crudeness or complexity depends on whether a low-grade or high-grade sensory mechanism is implicated, but we rarely, if ever, can say of it that it is confused, or made up of conflicting elements, or that it is of exaggerated intensity, or contains any excessive quality.

The problem of its origination is in reality that of hallucinations in general. A sensory aura is a hallucination, be it of the visual, auditory, muscular, gustatory, olfactory, viscerosensory, or any other sense class. Very valuable data bearing on questions of cortical localization have been furnished by a consideration of the sensory auras accompanying epileptic seizures occasioned by organic cerebral disease, instances of which might easily be provided from clinical experience. But we are concerned rather with the general problem of hallucinosis. The difficulty of deciding whether such phenomena are release phenomena or are irritative or excitative is, in my opinion, verbal rather than essential. Completely ignorant as we are of the process whereby function of a sensory mechanism is accompanied in consciousness by what is called a sensation, and, for that matter, of the point in a given sensory arc at which its activation becomes a conscious thing, we are not in a position to assert that a hallucination arises either because a sensory mechanism is "let go" from the control of some hypothetical inhibition, or because the mechanism is being activated by some usual or unusual stimulus. Even if inhibitory control is at first to be removed (by some equally unknown and speculative process), some excitation might still be necessary to "touch off" the prepared neural unit or system.

That hallucinations are common accompaniments of toxic or toxæmic states in no way helps us in our search for a physiological explanation of their development. When, as in the case of uncinate or temporo-sphenoidal epilepsy, a gustatory or olfactory hallucination is often associated with a visual or visuo-auditory hallucinatory state of a particularly elaborate, if certainly brief and fleeting, character, the most we can say is that this state arises in the course of the development of that abnormal physiological process which underlies all the phenomena of the fit, the aura included. Although all auras are psychical, rendering the separation of a so-called "psychical aura" meaningless, there is no good reason for supposing that this sensory component is in some fundamental way different from the motor components, as far as its development in the course of a fit is concerned, and none for imagining that its type, or recurring character, constitutes proof of the psychogenic nature of the epilepsy. Elaborate hallucinatory manifestations occur in persons who are half-drowned, half-hanged, half-suffocated; the hallucinations of uncinate epilepsy may be, and frequently are, as definite an index to the existence of organic cerebral disease as the twitching muscles of a Jacksonian case; the "déjà vu" phenomenon and the peculiar psychical condition of reduplicative paramnesia can occur as the aura alike of organic and of so-called idiopathic epilepsy. Elsewhere I have analysed these and analogous psychical manifestations of ordinary epilepsy at some length, and to this paper the reader is referred.

#### *The Question of Consciousness in Epileptic Fits.*

Some epileptic attacks are attended by loss of consciousness; others are not. Unconsciousness may supervene at the outset, or develop subsequently; it may be extremely brief in duration, or may continue for some time after all convulsions have ceased. Further, of itself it is no index to the severity of the fit; a severe Jacksonian attack may from first to last involve no loss of the senses, while a petit mal seizure may consist of little else than a transient conscious "blank," an "absence épileptique." With this considerable variability in the interrelation of unconsciousness and motor accompaniments the task of correlating their respective causes is not rendered easy.

The evidence for assigning the former to changes in the cerebral circulation is doubtless familiar to most physicians; it was excellently marshalled by A. E. Russell<sup>6</sup> in his Goulstonian Lectures of 1909, which should be read by all who seek an explanation of the difficult problems which epilepsy offers. Starting with this view, a line of argument in respect of the pathogenesis of epileptic symptoms has been developed by the same author, more or less as follows: Alterations in the general circulation afford an adequate explanation of ordinary fainting fits and syncopal attacks; they also explain the symptoms of more prolonged attacks in which cardiac, vasomotor, and cerebral phenomena can be observed; the suddenness of some faints, and the conversion of faints into fits, suggests the possibility of the epileptic fit itself having some origin analogous to that disorder of the cerebral circulation which causes unconsciousness. To this point I shall revert immediately; for the moment I may say that while transient cessation of that circulation is the most plausible explanation of sudden unconsciousness in epilepsy, certain difficulties remain. Consciousness is absent in negative functional cerebral states, such as concussion and coma; it is also absent during positive, excessive, functional cerebral states—for example, during the period of convulsions. Many clinical instances of the former are unaccompanied by any discharging or convulsive phenomenon whatever; conversely, a Jacksonian patient may exhibit many severe convulsive movements before consciousness is lost. It is undoubtedly difficult to elucidate both negative and positive states by reference to the same process—namely, disturbance of cerebral blood flow. General cerebral anaemia explains too much, as it were; with it the excitability of the cortex certainly diminishes, and absence, not excess, of movement should ensue. On the other hand, we might postulate (though we know no special mechanism for it) a cortical anaemia, producing unconsciousness, with retention of the circulation at lower neural levels, allowing activity of released subcortical neural systems; while such a hypothesis might conceivably provide an explanation of the features of the general fit (though, for reasons given above, I do not consider it can) it will not elucidate those of the Jacksonian variety. In view of the occurrence of degrees of unconsciousness in the epilepsies, and of the fact that negative and positive states do not proceed *pari passu* (as far as we can judge clinically), a simple theory of cerebral anaemia is insufficient for the variability of the phenomena.

#### *Relation of Epileptic Symptoms to the Cerebral Circulation.*

We may, however, in conclusion, pursue this matter a little further. The theory that the paroxysms of epilepsy are a sequel to and determined by contraction of cerebral vessels dates back at least as far as the time of Brown-Séquard. Hughlings Jackson<sup>7</sup> himself favoured the possibility of the paroxysm being caused by a local vascular contraction; he thought that "successions of different movements are developed by contraction of arteries"; "a convulsive paroxysm is developed by a stronger and more continued contraction" of the same arterial branches as, through coarse disease, are imagined to be producing abnormal and persistent changes of nutrition in the distribution of that artery; "it is, I speculate, through the arteries that sequence of movements is developed, whether those movements be spasm passing up the arm and down the leg, or whether they be the orderly sequences of movements in health."

More direct evidence, however, has taken the place of speculation. Russell<sup>5</sup> emphasizes the importance of the facts that the symptoms of the various stages of the epileptic fit are closely mimicked by those following heart-block in Stokes-Adams disease; that uraemic convulsions are indistinguishable from those of epilepsy and are almost certainly due to cerebral oedema, consequent increase of intracranial tension being followed by temporary failure of the cerebral circulation; that in some recorded cases of value temporary cessation of the heart's action (disappearance of radial pulse) has immediately preceded the development of a fit. A number of direct observations of the human cortex during an epileptic convulsion have been made by surgeons (Horsley,<sup>10</sup> Kennedy and Hartwell,<sup>11</sup> Leriche,<sup>12</sup> Horrax<sup>13</sup>). Sudden blanching of the cortex and pial vessels, and arrest of cerebral pulsation, is at once succeeded by pronounced hyperaemia and venous engorgement during the convulsive movements, according to the mean of the recorded observations. Reference might also be made to the apparent association of fits with disorder of the cerebral circulation in certain cases of Raynaud's disease, of which a number have now been reported (see a paper by H. J. Norman<sup>14</sup>).

While it would be unwise to ignore the cumulative effect of these differing lines of evidence, I do not think, after having given much consideration to the problem, that they can fairly be taken as showing anything more than that changes in the cerebral circulation accompany, in all probability, the march of events in an epileptic discharge. In my opinion Russell is justified in concluding that, even if vascular disorder is causal, it only carries the pathology of epilepsy one stage further. But I am not convinced that the association constitutes a causal relationship. The cerebral and general circulation is under the control of a vasomotor centre in the medulla oblongata; alterations in the whole cerebral vasomotor apparatus may be caused by dysfunction of that centre. Sudden loss of consciousness may not be of vascular origin, though accompanied by vascular change; the same pathological stimulus may act both on the bulbar vasomotor centre and on cortical neural elements themselves. That this would appear to be the case in respect of the unconsciousness following trauma is strongly suggested by the recent experiments of Knaauer and Enderlen<sup>15</sup>; and although the analogy with epilepsy is remote, it is well not to lose sight of the possibility of the circulatory phenomena of the fit—as observed when the cortex is exposed—being no more than a sequel to a central neural disturbance of function at the level of the medulla.

If, however, we are sufficiently convinced by the evidence sketched in outline above, we should still be at the stage of pure speculation in regard to the question of how transient cerebral anaemia—in some cases only, not in all—causes neural mechanisms to discharge; we should have to imagine a local cerebral anaemia for the phenomena of Jacksonian epilepsy; and I submit that many cases of local and sudden cerebral anaemia, as in monoplegias of embolic or thrombotic origin, are unaccompanied by any discharging phenomena whatever. Nor is the solution of the problem facilitated by ascribing the motor discharges to anoxaemia. Imperfect oxygenation recurring periodically, locally, and seemingly vanishing after an attack—how is such a process to be imagined? And how will any such theory account for the aura of a fit, which, as has been stressed above, unquestionably appears to partake of the nature of a normal, orderly, regularized, non-excessive function of a given sensory mechanism? Is neural activity accompanied by anaemia in the cerebrum of the normal individual?

The truth is that the gulf between the vascular and the neural is almost as impassable as that between the physical and the psychical. In this lecture, intentionally, no allusion has been made to clinical varieties of epilepsy of an unusual kind; if, however, the phenomena of so-called "epilepsia partialis continua" are considered, they may justifiably be used as an argument for the improbability of "discharging lesions" being based on persistence of an abnormal vascular state; they appear to resemble much more those of continuous excitation of a reflex neural arc by a persisting neural stimulus.

It seems to me reasonable to suppose that the crescendo character of the symptoms of the epileptic fit is due to

direct action of a neural system on collateral and lower neural systems; if a vascular factor is involved, I have tried to show the possibility of it itself being of neural origin. In some instances this may have a bulbar locus; in others there is as clearly a transcortical commencement for the attack. We come back, therefore, to the view indicated at the outset: any constellation of nerve cells in the neuraxis may become unstable; hence physiological varieties of "fit" are to be expected. It is evidently more correct, clinically and physiologically, to speak of "the epilepsies" than of "epilepsy," and this fact by itself should lead us to avoid giving our patients the impression that once a diagnosis of epilepsy is made it is tantamount to pronouncing their doom. On the contrary, increasing latitude in our conception of the condition should lead to modification of therapeutic pessimism.

## DIETETIC CONDITIONS WHICH INFLUENCE THE CALCIUM CONTENT OF SALIVA:

THE POSSIBLE SIGNIFICANCE OF THESE FACTS IN  
TUBERCULOSIS.

BY

C. LEE PATTISON, M.B., B.S.LOND., M.R.C.S.,  
MEDICAL SUPERINTENDENT, KING EDWARD VII HOSPITAL, SHEFFIELD.

### Introduction.

THE study of the etiology of dental caries and other defects of the teeth has usually centred around the chemical, physical, and bacteriological condition of the mouth, and, among other factors, saliva has been considered of importance in this connexion. However, in spite of the large amount of work by Miller, Röse, Pickerill, Marshall, Howe, Bunting, and many others, no relationship has ever been proved between the alkalinity of the saliva and the immunity to caries, as those upholding the acid-decalcification theory of caries might have hoped to establish.

Less work has been done on the calcium content of saliva, yet it is likely to be important. Among other possibilities it may hinder the removal of calcium from the teeth on the production of acid, or it may help in the hardening of the enamel after eruption, if this takes place, or it may aid in the arrest of caries.

The experimental work of May Mellanby<sup>1</sup> has proved that the structure of dogs' teeth, and probably also of human teeth, can be controlled by diet and environment. Foods rich in fat-soluble vitamin (for example, cod-liver oil, egg-yolk, milk, and most animal fats) tend to help the formation of well calcified, regularly arranged teeth, while other foods (for example, cereals, and especially oatmeal) tend to cause the development of badly formed teeth. Thus the total effect of a mixed diet is the outcome of a battle between these different dietetic influences.

On the basis of these facts Mrs. Mellanby and I started, three years ago, a clinical investigation to determine whether there is any relation between diet of the above-mentioned type and dental caries. Some evidence was obtained that a diet rich in fat-soluble vitamin not overburdened with cereal tends to prevent the onset and spread of dental caries more rapidly than does one containing little fat-soluble vitamin and more oatmeal and other cereal. These findings were published in a preliminary note (together with J. W. Proud, L.D.S.) in the *BRITISH MEDICAL JOURNAL* of August 30th, 1924.<sup>2</sup>

The investigation now to be described was carried out with the idea of seeing (1) whether there is any relation between the amount of calcium in the saliva and the rate of development and amount of dental caries, and (2) whether it is possible readily to alter the calcium in the saliva, especially by varying the diet in factors other than the calcium. As the work progressed, it was realized that many of the figures for calcium in the saliva were low compared with those obtained by other workers, and the possibility of this being due partly to tuberculosis was therefore considered.

In regard to the first point. The work carried out by Rüss<sup>3</sup> seems to indicate that, if anything, there is less calcium in the saliva of those people with fewer carious teeth; but that, if the amount of calcium in the ingested food is raised, then the calcium in the saliva may be in some cases also raised. Recently P. P. Laidlaw and Spencer Payne have worked out an accurate method for estimating small amounts of calcium,<sup>4</sup> and have also studied the calcium content of the saliva of people whose mouths vary from the point of view of carious teeth. No constant relationship, however, was found between the amount of caries and the calcium in the saliva. As will be shown later, the amount of calcium in the saliva may vary from week to week with small alterations in the diet, and probably also with other unknown conditions, depending on the metabolic state from the natal or even pre-natal period up to the day of observation. It would not be expected, therefore, to find a close relationship between the calcium of saliva, as observed on one or two occasions, and the amount of dental caries at that time. On the other hand, Mrs. Mellanby and I showed (in the paper referred to above<sup>2</sup>) that by raising the amount of fat-soluble vitamin in the diet we were able to delay the spread of caries. I shall now show that by increasing the fat-soluble vitamin in the diet the salivary calcium is raised. There would, therefore, seem to be some connexion between the quantity of calcium in saliva and caries, but to prove this definitely a more prolonged investigation would have to be made.

The second part of this inquiry—namely, the effect of diet on the salivary calcium—has given very definite results which will now be described.

#### Method of Estimating the Calcium.

The saliva was obtained by asking patients to spit into glass tubes three minutes after their mouths had been washed out with water. Various ways of estimating the calcium were employed, and the results recorded were obtained by two methods: (1) the alizarin method described by Laidlaw and Payne (L. and P.);<sup>4</sup> (2) the Kramer-Tisdall method (K.T.).<sup>5</sup> In practically all cases in which estimations were made by both methods the results agreed.

#### The Effect of Small Specific Differences in the Diet on the Amount of Calcium in the Saliva.

The amount of calcium in the salivas of patients having different diets was estimated. The diets were those described in the paper already referred to in the BRITISH MEDICAL JOURNAL of August, 1924.<sup>2</sup> The principal differences between the diets may be summarized as follows:

Diet A contains most milk ( $1\frac{1}{2}$  to 2 pints), cod-liver oil 6 drachms, and an egg daily, but no oatmeal.

Diet B contains least milk ( $\frac{3}{4}$  pint), no cod-liver oil and no egg, but 3 oz. of oatmeal, and olive oil (6 drachms).

It will be seen that diet A contains most calcifying vitamin and diet B the least, and that diet B is also peculiar in containing a large amount of oatmeal.

1. *Diet A*.—Twenty children were given diet A (more vitamin) and their salivas contained an average of 10.68 mg. of calcium in 100 c.cm.

2. *Diet B*.—Nineteen children were given diet B (less vitamin and more cereal) and their salivas contained an average of 4.68 mg. of calcium in 100 c.cm.

The following table gives examples of children fed on diets A and B.

Twelve patients on the ordinary hospital diet, which is intermediate, as regards the amount of calcifying vitamin, between diets A and B, contained an average of 7.79 mg. of calcium in 100 c.cm. of saliva.

| DIET A.  |                     |                 |                | DIET B.  |                     |                 |                |
|----------|---------------------|-----------------|----------------|----------|---------------------|-----------------|----------------|
| Patient. | Calcium.            | Method.         | Weeks on Diet. | Patient. | Calcium.            | Method.         | Weeks on Diet. |

#### Alterations in the Calcium Content of Saliva as the Result of Changes in the Diet Alone.

1. Some patients on admission to hospital were found to have an average of 3.07 mg. of calcium in 100 c.cm. of saliva. Their diets were unknown. They were now given diet A, with the result that the average amount of calcium was increased from 3.07 to 7.07 mg. in 100 c.cm. of saliva—for example, in the case of B. R. the amount of calcium was increased from 4.1 to 9.5 mg. in eight weeks.

2. Some patients who had been having diet B for ten weeks had an average of 4.47 mg. of calcium in their saliva. Later they were given diet A, and then the calcium was increased from 4.47 to an average of 12.07 mg.

3. Other patients on diet B, with an average of 5.15 mg. of calcium in the saliva, were given the ordinary hospital diet, and their calcium was increased, but only to an average amount of 8.95 mg.

4. Some patients on diet A, with an average of 12.02 mg. of calcium in the saliva, were later given diet B, when the amount of calcium was only slightly diminished—namely, from 12.02 to 11.67 mg. These patients were kept on diet B for four weeks only, as when this part of the investigation was attained the conclusion was reached that the general health of the patients on diet B was not so good as that of those on diet A. It is known that vitamin A can be stored in the body, and, presuming that this substance is of some importance in varying the percentage of calcium present in the saliva, it is possible that the quantity stored in the lengthy period during which diet A had been given was not sufficiently depleted to cause an alteration in the amount of calcium in the saliva in the four weeks on diet B.

#### Other Factors in Addition to Diet which might have Influenced the Results given above.

The average amount of calcium in the saliva of the children on admission to hospital was only 4.77 mg. in 100 c.cm. This is low compared with the figures obtained by other workers, which vary between 6 and 12 mg. per 100 c.cm. Therefore, various factors were considered which might be the cause of this low calcium content.

1. *Tuberculosis*.—The children all suffered with tuberculosis of bones or joints, in which varying degrees of decalcification had occurred. It was found that in most cases those children who had suffered from the disease longest had the smallest amount of calcium in their saliva on admission to hospital. The following are examples:

R. I. had had disease of the vertebrae for ten years; it had produced marked bony destruction, and was active on admission; his saliva contained only 0.90 mg. of calcium in 100 c.cm.

H. L. had had tuberculosis of the sternum and tarsus for three years, with sinus formation; his saliva contained only 1.60 mg. of calcium in 100 c.cm.

H. A. had had active disease of the hip-joint with abscess formation, but no bony destruction, for three months. His saliva contained 6.88 mg. of calcium in 100 c.cm.

However, there is no reason to believe that this factor was of primary importance in altering the relative amount of calcium in the salivas of the children in the diet groups; since this disease was common to all, and those children with the least active tuberculosis were usually put on diet B, and those who were suffering most severely from this infection were put on diet A.

2. *Water*.—All the patients were drinking Sheffield water, which has a low calcium content. To test this point the amount of calcium of a few Sheffield persons was obtained and compared with the amount found in a few London residents. The average quantity of calcium in the saliva of the ten Sheffield persons was: adults 8.07 and children 7.19 mg. in 100 c.cm. of saliva. The average quantity of calcium in the saliva of the ten London cases was: adults 10.61 and children 9.34 mg. in 100 c.cm. of saliva. Röse<sup>3</sup> carried out investigations with the idea of relating the extent of caries to the calcium content of the drinking water in different districts. He found that, on the whole, the children living in districts where the water was hard suffered less from caries than those living where the water was soft. The amount of calcium in the saliva of these subjects, however, was often less when the water was hard than when it was soft. Röse states that the full influence of a calcium-rich diet is only seen after several generations. It was found in the present investigation that the addition of calcium phosphate, calcium lactate, and calcium carbonate over a short period to the dietary of patients had no effect on the calcium content of the saliva.

3. *Age of the Patients*.—No definite relation was noticed between the age of the patient and the amount of calcium in the saliva.

4. *Hour of Collection*.—The amount of calcium in the saliva varied slightly at different times of the day in individual persons, but this variation was not constant.

5. *Rapidity of the Secretion of the Saliva*.—It was not found that the percentage amount of calcium varied appreciably with the rapidity of secretion.

6. *Hydrogen-ion Concentration*.—This varied between a pH of 6.5 and 7.5, and bore no relation to the amount of salivary calcium, nor to the degree of dental caries.

#### SUMMARY.

1. The amount of calcium in the saliva is influenced by diet. (a) A high calcium content of the saliva can be produced by a diet having a large fat-soluble vitamin content. (b) A low calcium content can be produced by a diet containing much cereal (especially oatmeal) and comparatively little fat-soluble vitamin, although the amount of calcium ingested in this diet may be the same as, or even greater than, in (a).

2. The calcium of the saliva is not increased by increasing the calcium of the diet over a short period.

3. Tuberculous children appear to have a lower calcium content of the saliva than normal children, and, on the whole, low resistance to the infection is accompanied by low calcium content. This relationship between resistance to infection and salivary calcium requires further investigation before it can be regarded as established.

4. It will be seen that the calcium content of the saliva is controlled by the same factors of special nutrition as those on which the calcification of teeth and bones also depend. If, therefore, caries of the teeth be influenced by the chemical composition of the saliva, then it is evident that the problem of dental caries is at least partially one of general metabolism. This point of view is corroborated by other results showing the relation of diet and caries, published elsewhere.

The expenses of this research were borne by the Medical Research Council and the Dental Board of the United Kingdom, to both of whom I wish to acknowledge my indebtedness.

## PLEURAL EFFUSION COMPLICATING PNEUMOTHORAX.

BY

L. S. T. BURRELL, M.D. CAMB., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN, WEST LONDON HOSPITAL; PHYSICIAN, HOSPITAL FOR DISEASES OF THE CHEST, BROMPTON.

PLEURAL EFFUSION is the most common complication of pneumothorax. If every patient with pneumothorax were examined daily with the x-ray screen there would be seen at some time or other in practically every case a small pool of fluid lying in the costo-diaphragmatic angle. Such small collections of fluid, however, are quickly absorbed; they come and go, and are of no importance. In speaking of pleural effusion I mean cases where the fluid at least covers the diaphragm and lasts more than a week, and I do not include those small transient effusions discovered accidentally by x rays.

Out of 309 consecutive cases in which I have successfully induced artificial pneumothorax for pulmonary tuberculosis an effusion formed in 128 (41.4 per cent.), and of these 47 (36.7 per cent.) are dead. Of the 181 cases in which no fluid formed, 57 (31.5 per cent.) are dead. Of the 128 cases the fluid remained clear in 92, and 27 (29.4 per cent.) of these are dead. In the other 36 cases the fluid was tuberculous pus, and 20 (55.6 per cent.) of them are dead. In time, no doubt, more of these cases will die of tuberculosis, but this applies equally to cases with and without fluid, so that the figures can be taken to show that, roughly speaking, cases which have clear pleural effusion do neither better nor worse than dry cases, but that if a tuberculous empyema forms the outlook is much more serious.

It should be clearly understood that these 309 cases do not include non-tuberculous cases, nor those where artificial pneumothorax was attempted but failed or was only partially successful. I have divided them into three groups: C1, where the disease was unilateral; C2, where there was some disease in the other lung but only slight; C3, where more than one-third of the better lung was affected. The last group consists largely of cases where artificial pneumothorax was induced as a last resort, and so the mortality is very high. Had the patients in this group lived longer many more would undoubtedly have developed effusion.

The following table shows the number of cases in the various groups which developed fluid.

|                 | C1.    |            | C2.    |            | C3.    |            |
|-----------------|--------|------------|--------|------------|--------|------------|
|                 | Cases. | No. Dead.  | Cases. | No. Dead.  | Cases. | No. Dead.  |
| Total ...       | 126    | 24 (19%)   | 125    | 47 (34.8%) | 48     | 33 (68.7%) |
| No effusion ... | 78     | 13 (15.6%) | 72     | 22 (30.6%) | 31     | 22 (71%)   |
| Clear fluid ... | 36     | 5 (13.9%)  | 45     | 14 (31.2%) | 11     | 8 (72.7%)  |
| Pus ...         | 12     | 6 (50%)    | 18     | 11 (61.8%) | 6      | 3 (50%)    |

In my series, effusion in the great majority of cases developed in the first six months and rarely occurred after the first year. The number of months after the induction of artificial pneumothorax when the effusion formed was:

|                    |          |
|--------------------|----------|
| 1 to 3 months ...  | 45 cases |
| 4 to 6 " ...       | 43 "     |
| 7 to 12 " ...      | 29 "     |
| 13 to 18 " ...     | 5 "      |
| Over 18 months ... | 6 "      |

Various explanations have been given to account for the frequency of pleural effusion in cases of pneumothorax. Irritation of the gas, its temperature, the repeated punctures of the parietal pleura, or the intrapleural pressure have all been described as playing a part in the production of fluid. In my opinion, however, these effusions are true tuberculous exudates, and in my experience they occur with equal frequency whether the gas is heated or not and whether air, nitrogen, carbon dioxide, or oxygen is used. We know that pleurisy is a common complication of pulmonary tuberculosis, and that it often leads to

adherent pleura. If the parietal and visceral pleurae are separated, as they are in cases of pneumothorax, one would expect effusion to form if pleurisy developed. In almost every case of spontaneous pneumothorax (where, of course, the disease has spread to the pleura) effusion develops. The cytology of the fluid is that of a tuberculous exudate, and although at first tubercle bacilli are not usually found, in long-standing effusions they can almost always be demonstrated. In none of my cases has any other organism been found. If my opinion is correct we would expect to find that in cases of non-tuberculous disease artificial pneumothorax would not be complicated by pleural effusion, and this is actually the case. In one of my cases of abscess of the lung a small pool of fluid appeared for a short time, but in none of my other 54 non-tuberculous cases of artificial pneumothorax did any fluid form—a percentage of less than 2, as against 41.4 for the tuberculous cases.

In spontaneous pneumothorax effusion is usually present, being absent in only 4 of my 22 cases, and these 4 all did well. As a rule, the fluid in spontaneous pneumothorax becomes thick tuberculous pus, the lung never re-expands, and the outlook is very serious; 13 of my 18 cases in which fluid formed are dead, and only 2 can be said to have done really well. I think thoracoplasty should be considered early in many cases of spontaneous pneumothorax, for unless the pneumothorax cavity can be obliterated by re-expansion of the lung it will sooner or later become infected, and the outlook is almost hopeless.

The treatment of pleural effusion complicating artificial pneumothorax depends on many factors, and each case must be taken on its merits. If the fluid is left it will usually cause obliteration of the pneumothorax cavity by pleural adherence and fibrosis starting at the bottom of the pleural cavity and working upwards. If this result is desired, therefore, the fluid should be left, but the patient must be kept under careful observation lest too much fluid develops and causes displacement of the mediastinum. Before this happens a sufficient quantity of the fluid must be aspirated. Many cases in which artificial pneumothorax treatment is allowed to terminate in this way do extremely well. As the lung is drawn out a satisfactory fibrosis develops over the diseased areas and the healthy parts of the lung begin to function once more. If, however, it is thought better to prevent obliteration of the pneumothorax cavity and to continue the refills it is very important to keep the pleural cavity dry by aspirating the fluid at each refill. Usually after one or two aspirations the fluid does not re-form. When fluid forms, a lung which was previously partially collapsed will become flattened out, and as the fluid accumulates the pressure rises, but it should never be allowed to rise sufficiently to displace the mediastinum. Sometimes the first indication of the presence of fluid is an unusually high intrapleural pressure. In one of my cases a pressure which was usually negative before a refill was found to be +5+10, and after giving 100 c.cm. of air it rose to +10+15. The pressure may, however, be negative in spite of the fluid, but a small refill will render it positive. For example, in one of my cases with fluid the pressure before refill was -10-6, but it became +17+19 after only 100 c.cm. of air had been given.

In replacing fluid the quantity of gas given must be much smaller than that of the fluid removed; roughly speaking, about one-quarter the quantity is required. In one case 225 c.cm. of fluid was removed and 200 c.cm. of air given, and the pressure was altered from -8-0 to 0+6. In another case where the initial pressure was -17-9, after removing 600 c.cm. of fluid it became -22-13, and after another 200 c.cm. had been removed it was -28-15. On adding 200 c.cm. of air the pressure at once rose to -16-9, another 200 c.cm. made it -10-6, and a third 200 c.cm. sent the pressure to -4-0. In one more case a pressure of +7+14 became -7+4 after removing 1,700 c.cm. of pus. It is not wise to allow the intrapleural pressure to alter too suddenly, and in replacing fluid with gas I think it is best to use two needles, the gas being introduced through one and the fluid flowing out through the other; by this method the pressure can be raised or lowered or kept constant at will. If it is wished to encourage the lung to re-expand the fluid should be removed without adding any gas, or if this is not thought wise

oxygen should be used, as this is absorbed more quickly than air.

If the fluid is purulent the case is very much more serious. The pus should be aspirated and the intrathoracic pressure kept as low as possible in order to help the lung to re-expand. If the lung does re-expand the outlook is hopeful, but if x rays show that there is no sign of re-expansion in the lung then we must face the fact that the patient will probably have a permanent pyopneumothorax and be liable to any of the many complications of that condition. In these cases I have washed out the cavity with saline, normal or hypotonic. I have injected 2 per cent. formalin in glycerin and other disinfectants into the pleural cavity, and in cases where the pus is thick I have injected some modifying fluid and rendered the pus more liquid and easier to aspirate, but the end is the same. If, therefore, the fluid is purulent and the lung fails to re-expand I think the best chance for the patient is to perform thoracoplasty as soon as possible. Before the operation, however, it is necessary to get the patient as fit as possible by washing out the pleural cavity and allowing him a period of rest in bed and good feeding. In most cases a preliminary operation for evulsion of the phrenic nerve is desirable. It is hardly necessary to add that active disease of the other lung is a contraindication to thoracoplasty, but in this case the outlook is almost hopeless. If, however, the better lung shows no sign of active disease I feel strongly that in these cases thoracoplasty offers the best chance to the patient.

## A CASE OF CHRONIC OBSTRUCTIVE JAUNDICE:

FOCAL NECROSES IN THE LIVER: MYELOID TRANSFORMATION OF THE SPLEEN.

BY

F. PARKES WEBER, M.A., M.D., F.R.C.P.,  
LONDON.

I HAVE recently encountered a case of chronic obstructive jaundice which presents some points worthy of comment. I will relate only the main points of the patient's last illness.

A man, aged 62, had chronic obstructive jaundice (complete obstruction) owing to primary adenocarcinoma of the hepatic duct at its junction with the cystic duct. He died on March 11th, 1926, after having had jaundice for only about one month. He had had occasional haematemesis, but at the post-mortem examination Dr. E. Bock found no lesion in the oesophagus, stomach, or upper bowel to account for it. The adenocarcinomatous growth was small and macroscopically scar-like. No metastases were seen. The liver weighed 2,300 grams (70½ oz.), and the intrahepatic bile ducts were distended with colourless bile. On microscopic examination sections of the liver were found to contain numerous foci, recalling by their small size and their irregular distribution the focal necroses of infectious diseases (enteric fever, etc.). They were distributed in various parts of the hepatic acini and contained necrotic liver cells and bile pigment; in many of them there were also quantities of large phagocytic cells (macrophages), and in some of them there were also collections of polymorphonuclear leucocytes, as if suppuration were threatening.

There had been no fever during life, and an infective origin for the focal necroses can hardly be maintained. It seems to me that these necroses are most probably a minor variety of what Horst Oertel<sup>1</sup> called "multiple non-inflammatory necrosis of the liver with jaundice," an example of which I described with a coloured illustration in 1909.<sup>2</sup> One possibility is that they are merely capillary "cholérhagies" due to overdistension of bile capillaries (apoplexia biliaris hepatis), but biliary focal necroses of a peculiar kind in the liver have been found in the absence of obstructive jaundice.<sup>3</sup>

Another point of interest was the enlargement of the spleen, which I have not yet mentioned; it had been a puzzling feature of the case during life. This splenomegaly had much diminished (as splenomegaly generally does) after haematemesis, but at the necropsy the spleen still weighed 770 grams (27 oz.); it was evenly enlarged, of

rather firm consistence, and red on section. Some of this enlargement might have been due to congestion, but some of it was certainly due to myeloid transformation. On microscopical examination the splenic pulp, not the lymphatic follicular tissue, was enlarged. In Giemsa-stained sections the pulp was found to contain great numbers of eosinophil cells and erythroblasts and a certain number of myelocytes; a few megakaryocytes were also found (in other sections). A blood count at the end of February, 1926, had given 3,416,000 erythrocytes and 5,450 white cells to the cubic millimetre of blood (of the white cells 89 per cent. were polymorphonuclear leucocytes, 5 per cent. were lymphocytes, 4 per cent. were monocytes, and 2 per cent. were eosinophils), and in a blood film taken on March 10th (the day before death) a few myelocytes were seen.

Since myeloid transformation (metaplasia) was first discovered by Dominici it has probably been more often observed in the spleen than in any other viscus. O. Naegeli, who gives an excellent review of the subject,<sup>4</sup> says that though Itami failed to produce myeloid metaplasia by experimental bleeding, Skornjakoff succeeded in obtaining this vital reaction by allowing sufficient intervals for recovery between the bleedings. Myeloid transformation of the spleen may (though of course it does not always) occur as a vital reaction to anaemias and cachexias of various kinds and various infective and toxic agents,<sup>5</sup> including even mercury perchloride.<sup>6</sup> It has likewise been observed as a compensatory reaction in cases in which the bone marrow has been reduced by osteo-sclerosis.

In conclusion, I must thank Dr. O. Bode (house-physician) for help in the clinical examination of the case, and Dr. E. Bock, and likewise Dr. J. W. McNee, for help in the pathological and histological examination.

### THREE CASES OF OBSTRUCTION AT THE VESICAL OUTLET AFTER PROSTATECTOMY.

BY

W. K. IRWIN, M.D., F.R.C.S.E.,

SURGEON TO OUT-PATIENTS, ST. PAUL'S HOSPITAL FOR GENITO-URINARY DISEASES.

A GREAT deal is written about the satisfactory results of prostatectomy, but comparatively little about the unsatisfactory cases. Yet it is by no means uncommon for obstruction at the vesical outlet to recur after a short interval, however carefully and apparently successfully the operation has been performed, and when there has been nothing to suggest malignancy. The following typical cases from my own practice may be of interest.

## CASE I.

In October, 1922, a man, aged 62, was sent to me complaining of difficult and frequent micturition of twelve months' duration. He stated that he was passing urine ten or a dozen times a day, and two or three times at night, the first few hours of recumbency being untroubled. His eye and knee reflexes were normal, and nothing unusual could be palpated in the renal and vesical areas. His urine was free from blood and from any sign of infection, but the residue left in the bladder after micturition amounted to 4½ ounces. On rectal examination the prostate was of uniform consistency, though not so elastic as usual, and the right lobe was definitely enlarged.

I did the ordinary (Freyer) suprapubic prostatectomy, but

experienced some difficulty in enucleating the enlargement, which was more fibrous than usual. I was particularly careful to divide any shelf existing between the prostatic and vesical cavities, and no abnormal symptoms showed themselves during convalescence. The suprapubic wound was completely closed and the patient was passing water by the twenty-second day. He stated that he had to strain more or less to get the urine away, but bougies and catheters passed readily into the bladder.

Five months later he returned complaining of great difficulty and considerable pollakiuria, so much so that he asked for something further to be done. Instruments would not pass owing to definite obstruction at the internal meatus.

I excised the scar tissue, opened the bladder suprapubically and freed it anteriorly, passed a metal bougie by the urethra into the prostatic cavity, put the patient in the Trendelenburg position, and inserted a Thomson-Walker retractor. I found that the internal meatus was greatly contracted, so, while my assistant pushed up the metal bougie, I cut away the intervening tissue with scissors until the instrument entered the bladder. The bougie was then removed, and I completely dissected away the partition between the vesical and prostatic cavities, leaving a large internal meatus. I then passed a big *coudé* catheter along the urethra, fastened it into the bladder and closed the vesical and abdominal wounds around a small suprapubic tube, which was removed three days later.

The bladder was irrigated with boric lotion and the catheter changed daily for a week, the urethra being irrigated as the instrument was withdrawn. On the eighth, ninth, and tenth days I passed a catheter in order to irrigate the bladder, but did not tie it in. On the eleventh day, when the urethra had had three days' rest, I again fastened a catheter in and continued to do so till the seventeenth day, when the wound was firmly healed and the patient passing urine more freely than for years previously.

I have seen him from time to time since, and introduced urethral instruments with a view to ascertaining whether there was any contraction at the bladder neck. Large *coudé* catheters pass without meeting any obstruction, and micturition is free.

## CASE II.

In November, 1924, I was asked to see a man, aged 65, suffering from retention, who gave a history of slight difficulty for about a year and great difficulty for two or three months. By rectal examination both prostatic lobes were moderately enlarged, but of uniform consistency. I passed a catheter and emptied the bladder gradually.

I performed a prostatectomy by the Freyer method as in the former case, the enlargement being hard, fibrous, and difficult to remove. Great care was taken to divide any shelf between the prostatic and vesical cavities, and the patient convalesced normally for some time, passing urine by the urethra at stool on the eleventh day. Three days later, and many times afterwards, he micturated independently of defaecation.

On the twenty-second day I found that I could not pass a catheter into the bladder, the point being arrested in the prostatic cavity. Only a small quantity of fluid could be introduced and that very slowly. I tried again on many subsequent occasions, always with the same result. Five weeks after the operation, when I was out of town, the suprapubic wound closed and the patient developed retention. The medical man who was called to see him passed a catheter. He thought the instrument was in the bladder when it was really only in the prostatic cavity, a mistake easily made in these cases. As he could not draw off any urine, he came to the conclusion that he had to deal with a case of suppression, and actually applied the treatment for that condition. After a short interval, however, the suprapubic wound burst open again and discharged a large quantity of urine.

I explored the vesical neck in the way already described, but after a thorough examination failed to find any opening. I completely removed the partition between the prostatic and vesical cavities, inserted a catheter into the bladder by the urethra, and treated the vesical and abdominal wounds as described above. The technique of the after-treatment was the same as in the former case. The patient made a rapid and uninterrupted recovery and has since passed urine without any difficulty.

## CASE III.

A man, aged 50, who had been leading a healthy country life, consulted me in April, 1925. He looked very fit, but complained of slight difficulty for four or five years and great difficulty for a month. He was passing small quantities of urine every hour both by day and by night. He found it very hard to begin the act, and the stream was a mere dribble. There was no haematuria, no sign of infection, and no history of gonorrhoea. The eye and knee reflexes were normal. On rectal examination the right lobe of the prostate was definitely enlarged, the left little, if at all. I passed a catheter, after meeting some obstruction in the prostatic region and drew off 6 ounces of residual urine.

I performed prostatectomy by the open method, as recommended by Sir John Thomson-Walker, and again found great difficulty

in enucleating the enlargement, which the pathologist described as a fibroadenoma without any trace of malignancy. I took great care to remove all the shell between the vesical and prostatic cavities; in fact I took away so much that my assistant was afraid I might open into the rectum.

For a time the patient did very well, and three or four weeks later, when the wound was healed, was passing water without the least trouble. Two months after the operation he began to experience some difficulty, more especially after a tiring day's work. I saw him in August, when he was complaining of great difficulty, the stream being small and intermittent. On passing instruments I encountered some obstruction at the internal meatus, though I managed to get steel bougies through. The dilatation gave him relief for some time, but he returned in February, 1926, when the suprapubic wound had broken down and formed a fistula. He was passing some urine normally with great difficulty, but most of it was coming by the suprapubic route.

I operated again on February 23rd and found a pin-point opening surrounded by dense scar tissue. I removed all the obstructing partition, made a large internal meatus, tied in a big catheter by the urethra and drained the bladder suprapubically. In three weeks the abdominal wound was healed and the patient passing urine without the least difficulty; in fact he does not remember ever micturating so easily and quickly before.

The points of special interest in these cases are:

1. All three patients complained of difficulty as their most prominent symptom before the prostatectomy.
2. The enlargement was in each case of the smaller and more fibrous type, a fact which supports the usually held theory that post-operative obstruction is commoner in this class of case.
3. The rapidity with which the wounds healed and the ease with which the patients subsequently passed water lead me to believe that in dealing with post-operative obstruction it is advisable to tie a catheter into the bladder by the urethra off and on until the suprapubic wound is healed. I have not found that the patient objects to its insertion and retention, if the instrument is changed and the urethra irrigated daily, and a good lubricant used.
4. While there is no doubt that the Thomson-Walker open operation is in the majority of cases greatly to be preferred to the old "blind" method, Case III proves that cicatricial contraction may cause obstruction and difficult micturition even after the more thorough procedure.

## STUDY OF AGGLUTINATION OF THE GONOCOCCUS IN MAN.

BY

C. E. JENKINS, M.R.C.S., L.R.C.P.,  
PATHOLOGIST TO SALFORD ROYAL HOSPITAL.

Much work has been done upon the agglutination of the gonococcus by means of the experimental inoculation of animals, and all workers appear to be unanimous that agglutinins are produced; the titre of such serums is high and there is general agreement that a titre of 1 in 1,600 is relatively easy to obtain.

It is on the subject of differentiation of type that divergence of opinion becomes evident. Some workers have been able to differentiate a number of types and subtypes; the precise number varies. Other workers have concluded that it is not possible to distinguish these types with any certainty by means of the agglutination test. A review of the literature has been given by Tulloch.<sup>1</sup>

An attempt to investigate this matter in the human subject presented an initial difficulty in that failure to obtain a positive result might possibly be due to the fact that the patient was infected with a type or strain of gonococcus not present in the polyvalent stock antigen. The only practicable method of overcoming this obstacle was to discard the idea of using a stock antigen and instead to use for each patient his own autogenous strain.

The following technique was therefore employed. Upon a patient presenting himself with a newly contracted urethral discharge a culture was made upon the medium always used in this laboratory and described by me in the *Journal of Pathology and Bacteriology* at various times. Next morning the growth was examined to ascertain that pure culture was possible, and subcultures made. These were incubated for twenty-four hours, examined

for contaminations, and, if satisfactory, made into a suspension of about 2,000 million per cubic centimetre with normal saline. The suspension was then violently shaken for a few minutes to break up any clumps present. The further steps in the preparation varied.

Four methods of treating it were tested. In the first neither antiseptic nor heat was used, the suspension being placed in the ice-chest immediately after shaking. The low temperature is quite sufficient to kill the organism. The second method was to heat at 55° C. for thirty minutes, then place in the chest. The third was to heat as before and afterwards add 0.1 per cent. of formaldehyde before storing in the ice-chest. Lastly, 0.1 per cent. of formaldehyde was added without preliminary heating. Immediately before the actual test was performed a sufficient quantity of antigen was taken from the bulk stock and passed through filter paper or a plug of wool in order to ensure a smooth suspension.

In the case of gonococcal urethritis a period of three or four weeks was allowed to elapse before taking a sample of blood. The purpose of the interval was to allow the patient an opportunity to develop any complications usual to that period—orchitis and so forth. It was thought that a more generalized infection would favour the production of agglutinins.

The test was performed the day after the blood was obtained, which meant that the antigen was then about twenty-four days old. The dilutions ranged from 1 in 10 to 1 in 320. The tubes were incubated at 55° C. for two hours, then put out on the bench at room temperature for another twenty-four hours. They were inspected at frequent intervals. The antigen and serum were stored and the test repeated at the end of a fortnight and again when the serum was six weeks old. This last procedure was to ascertain if any change in the serum took place with age.

The total number of cases examined was 21; they can be conveniently divided into two groups of 16 and 5 respectively.

The first group comprised the patients in whom the organism had been obtained from the urethra. Most of them had developed posterior urethritis, and four of them testicular lesions also, by the time their serum was collected. The result of the tests showed that the serum of every patient in this group was completely negative in all dilutions. Such a result has been obtained by other workers and has been explained on the assumption that agglutinins are not formed where the infection is localized or semi-localized.

The results obtained in the second group are therefore interesting. This group consisted of five cases of gonococcal arthritis. In each case the organism was obtained in pure culture from the joint fluid. Primary cultures are not difficult to obtain provided the fluid is inoculated as soon as it is withdrawn and not left to lie about the ward for an hour or so. The subcultures were made the next morning when the blood was collected and the serum separated. Immediately the antigen was ready for use the test was performed, and repeated at the same intervals as in the first group. The dilutions used were the same. Four of the serums were negative in all dilutions; the fifth was positive in a dilution of 1 in 10. This particular serum was tested again the next day for confirmation. Fourteen days later it was still positive, but was negative when tested at the age of six weeks.

At the present moment an original method of treating the serum is being tried and appears to offer better results in the second group, but the method is still under observation.

### CONCLUSIONS.

1. Agglutinins to the gonococcus are not produced in man when the infection is limited to the genito-urinary system.
2. In a generalized infection such as arthritis the amount of agglutinin produced is so small and uncertain that the agglutination test as ordinarily performed is of no value for diagnostic purposes.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL.

## CARCINOMA OF THE PROLAPSED CERVIX.

We are indebted to Dr. Leith Murray for directing our attention to the extraordinary rarity of this condition. Procidencia is practically confined to women who have borne children—not so much to women who have had hard labours as to women who have had successive pregnancies so rapidly that the uterus has never had time to get back to its normal post-partum size. Carcinoma of the cervix is also admittedly most common in women who have borne children, especially where the cervix has been lacerated in the process. Yet these conditions, individually common in the same class of case, very rarely coexist. It seems, therefore, that cancer is less liable to develop in the prolapsed cervix than in the non-prolapsed, otherwise the associated condition would be more frequent. Perhaps the character of the epithelium changes, making it less liable to a proliferative change. The following two cases may be worth recording. The first case shows carcinoma associated with prolapse, and the second case carcinoma developing soon after a long-standing prolapse was rectified.

## CASE I.

On July 22nd, 1922, I was called to see a widow, aged 72 years, who complained of abdominal pain. Whilst palpating the abdomen I found that the uterus prolapsed for about 3 inches outside the vulva. The cervix was a fungating, foul-smelling, cauliflower-like mass. She had kept the condition secret even from her own family, and she admitted that, although the prolapse was of thirty years' standing, the actual ulceration had existed for only two or three months. She had six children, all alive, and she had been a widow for five years. She was admitted into the Skipton Hospital in August for operation. Mr. Carlton Oldfield of Leeds saw her, and advised vaginal hysterectomy, which he performed on August 26th. She was discharged on September 25th, 1922, and remained quite well until September, 1924. She died on September 20th of that year, of cardiac disease, having shown no sign of recurrence of carcinoma.

## CASE II.

A widow of 53 had had four children, the youngest aged 26 years. Her prolapse dated from soon after her last confinement. There was no sign of old laceration, but there was a certain degree of superficial soreness of the cervix due to friction. The uterus could easily be replaced but not retained in position. She was admitted to hospital, and the inflammation of the cervix rapidly disappeared with rest and local treatment. There was no suspicion of carcinoma. An operation for perineal repair, along with ventral fixation, was decided upon, and this was performed on January 28th, 1914. She was discharged on February 28th, 1914. She enjoyed perfect health, and was most comfortable for the twenty months that she remained under my care. She then removed out of the district, but came back to see me early in 1917 complaining of a sanguineous vaginal discharge of two months' duration. Examination revealed inoperable pelvic carcinoma, apparently originating in the cervix uteri.

N. A. MACLEOD, M.D.,  
Honorary Surgeon, Skipton Hospital.

## HAEMATOMA OF THE ABDOMINAL WALL.

DR. FOTHERGILL's lecture on this subject, reported in the issue of June 5th (p. 941), covers many interesting aspects of a condition which has received very scanty consideration in surgical literature, apart from the recording of isolated cases. From the point of view of diagnosis, the presence of a haematoma in the abdominal parietes undoubtedly presents many difficulties, and it is especially, I think, when the condition occurs suddenly and acutely that the uncertainty in differential diagnosis between an intraperitoneal and extraperitoneal catastrophe arises. It seems to me (albeit from a somewhat meagre experience) that there is room for the inclusion of this condition in classifications of the differential diagnosis of acute abdominal conditions.

One case I have particularly in mind which, owing to the dramatic suddenness of onset and the exquisite tenderness associated with the swelling, made diagnosis almost impossible, short of surgical intervention.

Mrs. D., aged 83, was admitted to the Bolingbroke Hospital, S.W., complaining of intense abdominal pain. She was pale, collapsed, and in very obvious distress. The pulse was poor in volume, irregular, and the heart sounds faint. She gave a history of having, in the middle of a game of cards, gone to a cupboard

to take out a joint of meat, and, whilst lifting it out, was overtaken by violent abdominal pain and the sudden appearance of a lump in the lower quadrant of the abdomen. The rigidity of the abdominal wall made palpation very difficult, but the presence of an ill defined tender mass in the left hypogastric region, filling the left iliac fossa, was obvious. It was apparently fixed and hard, with a definite, though irregular, edge.

Both recti were rigid. It was difficult to exclude such conditions as torsion of the pedicle of an ovarian cyst, or of the left kidney or spleen, although actually the shape and position of the tumour negatived all these possibilities.

The swelling resembled nothing that one associates with abdominal viscera. The acuteness of the condition, and, partly, the uncertainty of diagnosis, were considered sufficient to make exploration advisable, in spite of the fact that the patient had been under treatment for several months for auricular fibrillation and chronic asthma and was therefore ill suited for the administration of a general anaesthetic.

Through a paramedian incision, under light ether anaesthesia, I opened the peritoneal cavity and found to my surprise a perfectly normal state of the abdominal viscera and the absence of anything like an abdominal tumour. Further dissection in the parietal wall opened into a large haematoma deep to the left rectus, burrowing between it and the posterior layer of the sheath, and also exposed some torn fibres of the rectus muscle itself. After turning out clot and employing a few deep haemostatic mattress sutures through the rectus the abdomen was closed. Recovery was uneventful and rapid.

Apparently in this case rupture of a segment of the rectus abdominis itself, together with some muscular branches of the deep epigastric artery, had occurred in a frail old lady after a slight effort.

I have notes of four other similar occurrences following some sudden effort, such as vomiting, coughing, etc.

The acuteness of the general condition, associated with pain and an abdominal tumour, serves to show the difficulty which exists in making a diagnosis, and seems to me to emphasize the desirability of remembering the possibility of such an occurrence and of distinguishing it from an acute intraperitoneal emergency.

Altrincham, Cheshire.

H. H. GELLERT.

## British Medical Association.

## CLINICAL AND SCIENTIFIC PROCEEDINGS.

## WITWATERSRAND BRANCH.

## TYPHOID FEVER: MANIFESTATIONS AMONG SOUTH AFRICAN NATIVES.

At the meeting of the Witwatersrand Branch of the British Medical Association on May 20th, held in the lecture hall of the Associated Scientific and Technical Societies Club, a discussion took place on enterica. Dr. A. J. MILNE (M.O.H. Johannesburg) contributed a paper on the public health aspect; Dr. A. BLOOM on the clinical aspect and treatment; Dr. M. BLEDEN on manifestations peculiar to children; Dr. A. S. STACHAN on the pathology and bacteriology; and Dr. A. FREW communicated a paper by Dr. H. T. H. BUTT and himself on manifestations peculiar to natives. Both can speak with special authority, as each has under his medical care large numbers of mine natives: the former being medical officer to the East Rand Proprietary Mines, Ltd., the latter to the Randfontein Estates Gold Mining Co., Randfontein. The experience of Drs. Frew and Butt is necessarily derived from adult male natives, which somewhat limits the possibility of comparison with whites. Nevertheless they were able to give a very interesting account (summarized below) of the disease as it occurs among the natives on the mines.

In the first place it is to be assumed that typhoid fever occurs in the native territories, as a fair number of natives arrive on the mines with the disease developing or already developed. As to the mines themselves, on some the disease is more or less endemic, with occasional outbreaks that may be described as epidemic. Amongst the 10,000 natives on the East Rand Proprietary Mines during 1922-25 no case was recorded in seven of the forty-eight months; at Randfontein, with 16,000 natives, no case was recorded in eighteen months of the same period. On the East Rand Proprietary Mines the successive annual figures were 42, 46, 40, and 38. At Randfontein they were less uniform—namely, 9, 45, 21, and 36. The prevalence is greatest on the mines with the bucket sanitary system. One source

of infection believed to be of considerable importance is the water tapped underground on the mines, which many natives, despite warnings, persist in drinking. The same applies to the industrial water used for washing down slope faces, etc. Though they may not actually drink this water they see no objection to storing it in their mouths for lubricating the holes they are drilling. Carriers constitute a great difficulty. An attempt is being made to search for these among all the natives who come into contact with food supplies in the compounds; but it is questionable whether the single examination of urine which is suggested will be sufficient.

A very remarkable feature of the disease among natives is that quite frequently a perforation will actually occur before the man feels sufficiently ill to report at the hospital. In one case of sudden death the district surgeon, finding *post mortem* a perforation with its accompanying peritonitis, suspected neglect, until it was proved to him that the native had done a full shift of work the day before and regularly for a week before that. Once a native was picked out with a perforation and peritonitis from amongst a group of discharged "boys" (all male natives of whatever age are "boys"); he was awaiting his turn to be passed out to go home to his kraal. He died in hospital within twelve hours. Most mine medical officers are familiar with such cases, which, with the native's habit of occasional defaecation and promiscuous urination underground and on the surface, must contribute considerably to the spread of the disease.

Differences in the symptoms from those observed amongst whites are of interest. Petechiae are of very little importance in diagnosis. They are difficult to recognize on the dark skin, and the native is very liable to various sweat rashes produced by the combination of moisture and heat obtaining underground. Loss of appetite apparently never occurs. The native is always a hearty eater, and must be extremely ill before he turns away from a good meal. That he has lost his appetite is not a confession that a native has been known to make. Splenic enlargement cannot be used diagnostically, for the reason that many natives, particularly those from East Coast tribes, are impregnated with malaria and have chronically enlarged spleens. Phlebitis ("enteric leg") occurs, but not so frequently as in whites. This is in keeping with the rarity of varicose veins amongst mine natives; their venous systems are in good order. The diagnosis must be reached by a process of elimination, with the temperature chart alone pointing the way; and here, also, complications are caused by certain undulant fevers common to most tribes, but particularly the Xosas, probably lice-borne infections. The Widal test is negative as often as positive, even when taken two or three times in cases of undoubted enteric.

Prognosis is graver than in whites, which is to be attributed very largely to the fact that the patient presents himself so much later in the course of the disease. On the East Rand Proprietary Mine the mortality during five years has averaged 33 per cent., never falling below 21 per cent., while at Randfontein the average is even higher—47 per cent., never falling below 33 per cent. This is in very strong contrast with the hospital mortality of 7 to 20 per cent. quoted by Osler.

From time to time prophylaxis has been considered; but the unfortunate mine native already has to undergo much in the way of vaccination and inoculation, and mine medical officers are loath to add further to his discomfort. Apparently there are difficulties in the way of combining the pneumococcal vaccine with T.A.B.

Medicinal treatment runs on the same lines as for whites. Dietetically there is the difficulty of overcoming the reluctance of the native to undergo what he looks upon as a process of starvation. "Laparotomies for perforation have small chance of recovery, as the native can seldom be made to see the necessity for an operation unless he is suffering great pain, and in any case he wants a day or two to think it over, and discuss it with his brothers. Even if you obtain his consent early he still may die, and his brothers have been known to raise a riot in a compound and go on strike because their brother went into hospital with only a headache, and died because his abdomen was cut open."

## Reports of Societies.

### THE FUNCTION OF THE TESTES.

At a meeting of the Section of Urology of the Royal Society of Medicine, held on May 27th, Mr. T. E. HAMMOND (Cardiff) read a paper on the function of the testes after puberty.

After referring to the difficulties experienced in proving whether any changes had occurred, Mr. Hammond gave an account of seven cases of castration in which both testes had been removed for tuberculosis. In none did any reversion to the so-called neutral type take place, and sexual desire and power was retained for some time. He believed that many current views about the function of these glands were based on ideas handed down from the past. He referred to the influence which sex worship had played among all nations, and said that the stigmas fastened upon the eunuchs were not necessarily due to the absence of testes. Eunuchs were in power in the Roman Empire at times that were characterized by debauchery and licentiousness, which prevailed among all the people. Many of the failings of eunuchs at that time were to be attributed to their Oriental extraction and to their upbringing; for character depended more upon heredity and early training than upon an internal secretion. They had been denounced by Gibbon, who seemed to believe that "testes make the man"; in this respect he might be looked upon as a forerunner of the rabid endocrinologist of to-day. In Mr. Hammond's opinion the work of Brown-Séquard had been given too much prominence. The preparation of the testicular extract was not difficult, and, as a hypodermic injection required but little skill, the fact that Brown-Séquard's results had not been obtained by others seemed to be conclusive that the improvement in his cases was due to suggestion. Whenever any effect followed castration in man, it was always attributed to the loss of an internal secretion. The possible action of shock from the operation and the effect of a deformity and loss of power had been ignored. That these factors might have some influence was illustrated by cases that were recorded. As enlargement of the prostate was often associated with impotence or increased sexual desire; these conditions had been attributed to changes in the testes. The urinary symptoms were always regarded as secondary to the prostatic enlargement. In the same way the sexual symptoms were explicable, if they were regarded as secondary to the pressure of the enlarged prostate upon the ejaculatory ducts. That the increased sexual desire was really a sexual irritability was shown by the fact that no relief followed coitus. It was responsible for many of the sexual aberrations seen in elderly men who had previously lived moral lives. In recent years the functions of the testes had received much prominence owing to the claims of Voronoff and Steinach for the rejuvenating action of these glands. In Mr. Hammond's opinion their practice was based on erroneous deductions, and their findings were not conclusive. When the therapeutic activity of the internal secretion of the testis was investigated it would be found that, no matter how the treatment was applied, successes always followed. The affections treated were most varied in their pathology and causation, and were as numerous as those put forward by Coué as suitable for auto-suggestion. Such claims followed all new methods of treatment, and were due to the failure to appreciate a fundamental principle—namely, that with all therapeutic measures faith and hope were of primary importance; but in the process of rejuvenation the greatest factor was not vasectomy.

Mr. Hammond's conclusions were as follows: For years it had been held that without testes no impregnation could take place; and from his series of cases it appeared that this still held true. The power attributed to the internal secretion was probably overestimated. The internal secretion was probably essential for the true development of the secondary sexual characters; when once these were formed, removal of the glands led to but little change. It had some action in stimulating sexual desire and power. It probably had some action upon metabolism.

as shown by the tendency to obesity after castration. It might have some action upon that elusive condition known as general tone. It had not that action upon the mental and physical well-being which had in recent years been claimed for it.

### AMENTIA AND CRIME.

THE annual meeting of the Medico-Legal Society was held on June 15th, with the President, Lord Justice ATKIN, in the chair.

Sir JOHN COLLIE read a paper entitled "A study from a medical and legal point of view of the case of John Perry, executed in 1660." William Harrison, aged 70, steward to Lady Campden, set out to collect rents, and, failing to return, his servant, John Perry, was sent in search of him. Later, Perry made a "confession" implicating his own brother, Richard, and his own mother, Joan, in the murder of Harrison. Although the body of Harrison was not recovered, the three were tried for murder before Sir Christopher Turner at Gloucester Assizes, but the judge refused to convict in the absence of direct proof of death; at the following assize, however, Sir Robert Hyde sentenced the three Perrys to death. To the end the mother and Richard protested their innocence. Sixteen years after the executions Sir Thomas Overbury sent to Dr. Shirley, physician to Charles II, a signed statement by William Harrison, who had returned to his native village sixteen months after the executions, detailing his seizure by highwaymen on the night of the murder. He never saw the Perrys at all.

The fatal error in the case was conviction in the absence of recovery of the body. As to the medical side of the case, Sir John Collie did not believe that any sane man would simultaneously commit the crimes of matricide, fratricide, and suicide. Was John Perry a mental defective? Amentia was more common than was generally supposed. It had been estimated that 20 per cent. of our prison population showed the stigmata of mental deficiency. Tredgold's investigations in Somersetshire led him to conclude that 10 per cent. of mental defectives evinced antisocial tendencies. Many aments could do fairly complicated work, with or without supervision. They could, for instance, take care of animals, but they could never control others. They jogged along, or gravitated to a home for defectives or to prison. Those who lacked moral sense did not always lack wisdom, and were, therefore, of greater potential evil to the State. Serious misconduct was one of their chief characteristics. In children it was sometimes difficult to recognize whether the defect was more moral or intellectual. If the children escaped segregation when young, later in life they might exhibit their fatal defect in some cold-blooded murder or terrible crime. This moral insanity was sometimes, apparently, latent, and only awaited its opportunity. Sir John Collie thought that many of these crimes lay at the door of the newspaper proprietors. The lurid details of one crime led in time to others. A visiting J.P. to the Glasgow prison told him that, being struck by the refined physiognomy of one prisoner, he asked him who he was. The reply was, "Hush! I am Morrison." It was a case that had made some little stir; the man had been sentenced to ten years' penal servitude for embezzlement, and seemed proud of it. In a similar case at Broadmoor the man who had committed a terribly cold-blooded murder posed as a hero, proud of himself. The prison doctor, when asked what was the form of mental disease which had saved the man from the gallows, replied, "Moral insanity." If John Perry was a moral defective, why was this defence not set up at his trial? The answer was that the tragedy occurred in 1660, and that even in 1926 such a plea might not always be successful. If Perry was sane he knew he was innocent, and also that his mother and brother were innocent. It might be argued that Perry was an hysteric.

But hysterics scarcely ever came to any harm. The hysterical state would not have lasted so long, and, if present, would not have remained so long unchanged. Had it been an hysterical condition Perry would have broken down either at the trial or at the executions. Again, it might be that Perry suffered from delusional insanity. If this were so his story would have varied much more than it did, and it certainly would not have stood inquiry or cross-examination. After a time Perry thoroughly believed the story he had evolved—it became a true delusion. Lastly, was Perry suffering from dementia præcox, which was most common between the ages of 15 and 30? Perry's story was a typical phantasy, like the charges which girls sometimes made of having been assaulted. It was typical of dementia præcox that its victims were emotionally apathetic. Could apathy be more callous and inhuman than to condemn a mother and a brother to a horrible end and be quite regardless of their appeals? Sir John Collie inclined towards the diagnosis of "moral insanity," but he had not arrived at a definite conclusion.

Sir HARRY STEPHEN said that the story depended greatly on the truth of Overbury's letter to Shirley. Did Harrison really come back? Did Harrison really suffer as he alleged, or was it a put-up disappearance whereby Harrison's son should step into his father's shoes as steward to Lady Campden? The speaker said he always distrusted "confessions." Further, he did not think it always necessary to produce the body where a murder had been committed before a sentence could be passed. Crippen was convicted after a mere fragment of skin had been found.

Lord Justice ATKIN said he had made inquiries at the Record Office, and the assize clerk had, he observed, made an entry against the names of the Perrys: "puts," that is, "puts himself on the county," which meant trial by jury, and "sus," that is, suspended, or hanged. Perhaps research in the parish registers of Campden and Bourton might elicit further facts concerning what he considered "our most horrible judicial tragedy."

Mr. BERNARD O'CONNOR, Dr. WATSON, Mr. ROLAND BURROWS, and Miss LETITIA FAIRFIELD also took part in the discussion.

## Reviews.

### THE SECRETION OF URINE.

THE second edition of *The Secretion of the Urine*,<sup>1</sup> which has just appeared, was almost the last work Professor A. R. CUSHNY did, for he had just completed the revision of the proofs at the time of his sudden death early this year. The first edition of the book appeared nine years ago, and during the interval a considerable amount of research work has been done on the subject, although no very revolutionary discoveries have been made. The present edition gives a full account of all this recent work, but the author concludes that the general result of the work done during the last decade has been to confirm the theory of urinary secretion put forward in the first edition of his book. This theory supposes that the glomeruli act as filters, filtering off the non-colloidal constituents of the plasma, and that the tubules absorb from this filtrate a fluid of practically fixed composition. As a result of this mechanism some substances have no threshold and are entirely excreted, while others have a high threshold (for example, sugar) and normally are entirely reabsorbed, while most substances lie between these extremes and are excreted in varying amounts.

It is pointed out that the experiments of Wearn and Richards, who succeeded in actually tapping the glomeruli of the frog's kidney with fine capillaries, and in analysing the minute quantities of fluid thus obtained, provide direct evidence for the view that the glomeruli act as simple filters. The experiments of Starling and his co-workers on the heart-lung-kidney preparation of the dog, on the other hand, are difficult to explain on Cushny's theory, though

<sup>1</sup> *The Secretion of the Urine*. By Arthur R. Cushny, M.A., M.D., LL.D., F.R.S. Second edition. Monographs of Physiology. London and New York: Longmans, Green and Co., Ltd. 1926. (Med. 8vo, pp. xii + 288; 39 figures. 16s. net.)

ie did not consider that these results offered any insuperable objection to his view.

The fundamental nature of kidney activity has been the subject of controversy for more than half a century, and it is unlikely that Cushman's theory represents the final and absolute truth. It is, however, the first coherent theory of kidney secretion which accords with most of the known facts; it has also the merit of simplicity. Considering the rapidity of the present advance in physiological knowledge it is very satisfactory that the theory should have stood the test of ten years so well.

The first edition of this book was recognized as the clearest summary of our knowledge of the difficult subject of kidney secretion that had appeared, and this new edition fully maintains the reputation of its predecessor. The sudden death of the author in the prime of his life is an irreplaceable loss to medical science.

### MALIGNANCY AND EVOLUTION.

In his latest book, *Malignancy and Evolution*,<sup>2</sup> Mr. MORLEY ROBERTS sets out to justify the claims of philosophy as an engine of research and, at the same time, to plead earnestly for the restoration of the philosopher to a recognized place among scientific workers. Without laboratory training, and dependent for his facts on others, he nevertheless handles his tools as if he had been accustomed to them from youth upwards. In this dexterity Mr. Roberts stands almost alone among "outsiders." There are numerous examples of medical men and of biologists who have turned from medicine and from science to fiction and to letters, but in turning from fiction, letters, poetry, and painting to sound the depths of modern biology Mr. Roberts has broken all precedent. If we follow him through his later work we see him becoming more and more involved in the deeper problems of life, and it becomes plain that he is really a man of science who sought for expression through the medium of fiction and of narrative. He had reached mid-life before he turned to the writings of scientific men in search of facts which would assist him in unravelling the intricacies of human nature and of human behaviour, especially as manifested under the conditions imposed by modern civilization. He studied works on sociology, then on psychology, and later, still in search of further light and to serve him as a porayer of human life, entered the great fields of general biology. He there came to perceive for himself that the animal body—and it was man's body on which he concentrated his attention—was in reality a colossal society of microscopic units.

It detracts in no wise from the merit of Mr. Roberts's intuition that Herbert Spencer had made the same discovery fifty years before him. Like Spencer, Mr. Roberts soon realized that the student of human societies had little or nothing to learn from the professor of biology, but that, on the other hand, the sociologist could provide effective assistance to the professed biologist. The size of the living units which make up a society, Mr. Roberts declared, is immaterial; they may be microscopic in size or they may be as big as elephants; if they are massed into societies there must be an elaborate machinery for the regulation of the conduct of each individual of that society. The rules and conditions which regulate human society are recognized; there must be, Mr. Roberts inferred, a corresponding, if more elaborate machinery for regulating the behaviour of the uncountable millions of units which make up such a vast society as that represented by the human body. He therefore, at an early date, commenced the search of physiological literature for evidence of this machinery; the nervous system was recognized, as it had been by previous inquirers, as representative of central government; the discovery of hormones, the action of endocrines, the results obtained by experimental embryologists, and effects produced by one tissue on another when grown in experimental cultures and the stimulating effect produced on such cultures by embryonic

juice, came, all of them, as grist to his mill. He searched the literature dealing with immunity, with repair, with atrophy and hypertrophy, and with the formation of tumours of all kinds, to see if any parallel were to be found to the conditions which produce rebellion and disorganization in human societies. The process of invasion, the outstanding feature of all malignant tumours, was, he found, present in all living societies. The invasion of one tissue by another is manifested at every stage in the development of the embryo; it is a part of Nature's evolutionary machinery and by no means restricted to the manifestations of malignancy. He has ransacked the literature of evolution and of genetics for conditions which produce structural and functional changes in the animal body, leading on to the modification of one species and the extinction of another. He gives his reasons for believing that pathological stresses and processes are normal parts of the machinery of evolution. Tumour formation, in Mr. Roberts's opinion, is both normal and physiological, for he regards the liver, the pancreas, and every organ in the body as having come into being as a developmental or physiological tumour. The origin of cancer he regards as the same problem as the origin of the placenta; if we could ascertain the conditions which cause the liver to grow out, tumour-like, from the duodenum, we should probably be in a position to explain the origin of an enchondroma growing from the end of the femur. All are but variations of the same problem—the problem of growth. Whoever discovers the machinery of cancer production will, at the same time, throw a flood of light on the machinery of growth—for that which serves the one is the same as serves the other.

Thus the conversion of Morley Roberts the novelist into Morley Roberts the biologist has not been by way of sudden mutation, but by a process of gradual evolution. He strayed into the biological fold in search of facts to aid him in elucidating sociological problems; he ultimately pitched his tent within this fold to apply to the problems of biology his sociological doctrines or laws. In *Warfare in the Human Body* (1920) he enunciated his sociological doctrine of "hostile symbiosis"; in *Malignancy and Evolution* this doctrine is applied to the explanation of all disorders of growth and development, particularly to the elucidation of cancer and of sarcoma. Hostile symbiosis is a basal law, he maintains, in all massed communities. Even in the best ruled and most law-abiding society there is ever a rivalry of interest and an unceasing "give and take" on the part of the sections of the community which represent these divergent interests. Even the best of neighbours in the best regulated municipalities have steadily to maintain their rights, tacitly or openly. We may live like gentlefolk, yet we cannot be units of a society unless we are "hostile symbiotes." The relationship between a living cell and all its equally living neighbours, Mr. Roberts maintains, is of the same kind: the epithelium which covers the skin is ready to take advantage of any weakness on the part of its mesoblastic neighbours which make up the underlying corium. Between neighbouring cells and between neighbouring tissues there exists, throughout the entire body, an armed neutrality or hostile symbiosis. Without such a state of matters there could be no adaptation to environment and no evolution of new forms. Thus tumour formation, benign and malignant, is just such growth reactions as are to be expected if Mr. Roberts's theory of hostile symbiosis is right. They are such manifestations as are to be expected if the government of the body fails—the government represented by the nervous system, the endocrines, and those more primitive and numerous substances to which Mr. Roberts gives the name of co-endocrines. Local tissues, he holds, are always ready to break through their normal bounds, being stimulated thereto by excitants or irritants, which may take the form of radiations, toxic substances, or substances introduced from without the body or manufactured within its tissues. Mr. Roberts succeeds in fitting all manifestations of growth, ordered and disordered, within his philosophical scheme of biology. It is a book which the professed biologist and pathologist should not pass by unread.

<sup>2</sup> *Malignancy and Evolution: A Biological Inquiry into the Nature and Causes of Cancer*. By Morley Roberts. London: Eveleigh Nash and Grayson, Ltd. 1925. (Demy 8vo, pp. viii + 319. 18s. net.)

## POTT'S PARAPLEGIA.

MADAME LE [sic] DR. SORREL-DEJERINE is the daughter of one distinguished surgeon and the wife of another. Her husband, Dr. Sorrel, is well known for his work at Bercé in the treatment of surgical tuberculosis. At the Maritime Hospital at that place Mme Sorrel has in four years had the opportunity of studying and recording forty cases of paralysis complicating vertebral disease.<sup>3</sup> Of these cases four died, and some of the others left the hospital and were lost sight of. Like previous writers on this subject, Mme Sorrel observes that paralysees are very rarely due to compression by bone, very often to an abscess inside the spinal column, and only sometimes to pachymeningitis. While most cases of Pott's paralysis tend to spontaneous cure, those that are the result of pachymeningitis are not suitable for surgical treatment and very generally incurable. Such cases begin later in the course of the disease, and develop more slowly than do cases of paralysis due to oedema or abscess.

The author thinks that all operative surgical treatment of Pott's paraplegia is useless, but it is to be noted that a number of the cases recorded were treated with Albee's bone grafts. This operation, while it does not directly react upon the paralysis, favourably affects the suppurative process, and may cause relief of pressure on the cord. The anatomical and pathological aspects of the matter are well dealt with in this book, and the considerations which should guide the surgeon in his prognosis are adequately set forth and considered. The illustrations are good. There is no index.

## DYSPNOEA.

THE fifth of the "Medicine Monographs" series is on *Dyspnoea*,<sup>4</sup> by Dr. J. H. MEANS of the Harvard Medical School and the Massachusetts General Hospital, Boston, who deals with this complicated subject from a sound physiological standpoint, and endorses Meakins's definition of dyspnoea as "the consciousness of the necessity for increased respiratory effort." The causes of dyspnoea are considered to arise at various points in the chain of events which keep the tissue cells in an environment best suited to their normal life. Beginning, therefore, with the basal metabolic rate, the modifications due to exertion, excitement, food, and disease are mentioned, and it is pointed out that in leukaemia the metabolic rate may be as high as in exophthalmic goitre. The laws governing the transport of gases are illustrated by dissociation curves of carbon dioxide and oxygen, and the rate of blood flow both at rest and in work by observations made with Newburgh on the author's own circulation. In the section on the efficiency of the pulmonary bellows the volumes of the anatomical and physiological dead space are discussed and the part played by nervous control is considered. The chapter on dyspnoea associated primarily with increased metabolism deals with the physiological, as in exertion, and pathological forms, as in thyrotoxic conditions.

When dealing with dyspnoea associated primarily with the disturbance of the acid-base balance, the term "acidosis," "much abused not only by clinicians but by physiologists," is defined as a condition in which acids other than carbonic are present in the blood in excess of their usual concentration. The diabetic patient with acidosis rarely has dyspnoea, at least when at rest, and may manifest pure hyperpnoea as in a normal person in moderate exercise; a nephritic with acidosis is, from the frequency of some handicap to ventilation, such as pulmonary engorgement or oedema, more likely to have dyspnoea. In 1914 the author confirmed Professor J. Barcroft's proof that acidosis may occur in cardio-renal disease, but found little if any relation between the intensity of the acidosis and the dyspnoea, a discrepancy which may in part be due to changes in the sensitivity of the respiratory centre. The evidence for Haldane and Douglas's view that Cheyne-Stokes or periodic breathing

is due to oxygen want is recognized as conclusive, though in discussing cardiac dyspnoea the relationship is stated to be far from simple. The dyspnoea of heart disease and of pneumonia are considered separately; the fundamental fault for the first is obviously failure to maintain the adequate rate of blood flow; in mitral stenosis especially there is stagnant anoxaemia of varying degree due to slow blood flow; in cardiac failure there may be arterial or anoxic anoxaemia due to defective aeration in the lungs; in congenital heart disease the most extreme degrees of either arterial or venous anoxaemia occur, due not to changes in the lungs, such as oedema, as in cardiac failure, but to the cardiac malformation. In pneumonia the factors responsible for dyspnoea are increased metabolism, anoxaemia, perhaps acidosis, and the diminished efficiency of the lungs with restricted vital capacity, necessitating rapid shallow breathing, which is not only uneconomical but may increase anoxaemia.

Some remarks on the treatment of the symptom dyspnoea, based on the known morbid physiology, such as the indications for reducing the metabolic rate by rest, for improving the muscular action of the heart by digitalis, and for promoting gas exchange in the lungs by the administration of oxygen, bring this admirable monograph to a close.

## NOTES ON BOOKS.

THE monograph on transfusion of the blood,<sup>5</sup> by Dr. BURGHARD BREITNER, first assistant in Professor Eiselsberg's surgical clinic at Vienna, is in two parts. In the first, which is devoted to the practical side of the subject, the writer discusses the value of transfusion compared with other methods of replacing loss of blood, the determination of blood groups, the dangers of transfusion, the action of transfusion, the various methods, especially those of Oehlecher and Percy, and the indications for the procedure. The second part deals with theoretical considerations connected with blood grouping, including its anthropological significance. The summary of the work is followed by an historical note and an exhaustive bibliography.

*An Explanation of Hydrogen Ion Concentration: The Capillary Method for the Determination of Acidity and Alkalinity in General Practice*,<sup>6</sup> by Dr. H. A. ELLIS, is a small pamphlet whose purpose is explained by its title. The subject is discussed in very simple language, and it is shown how easy it is to determine the reaction of any body fluid by using a capillary set, consisting of a series of capillary tubes filled with indicator dyes at varying hydrogen ion concentrations; spare tubes and dyes are provided, and by means of this method the reaction of a drop of fluid can be estimated in a minute or two.

*The Basis of the Golf Swing*<sup>7</sup> is the title of a book by a medical writer, Dr. JAMES FORREST. The author claims, through his knowledge of anatomy, to have discovered the secret of the golf swing, and so to revolutionize the teaching of the game. There is, however, little, if any, reference to anatomy in its pages, and the author's secret is disclosed in a somewhat complicated dissertation on the use of the wrists and the manner in which they should be turned during the upward and downward movements of the club. His theory of the swing and the use of the wrists is, however, well illustrated by numerous photographs, taken at rest and during a swing. Golfers may or may not appreciate his teaching, but the golfer who endeavours to improve his play by considering how his wrists are turning at the proper moment (backwards, forwards, downwards, upwards, to the left or to the right) will no doubt pass through a bad and distracted phase. His condition will not be unlike that of the centipede on being asked which leg went after which!

Volume 50 of the *Transactions of the American Gynecological Society*<sup>8</sup> is edited by Dr. A. H. Curtis and contains the address of the president, Dr. H. C. Taylor, and numerous well illustrated papers on gynaecological subjects.

<sup>5</sup> *Die Bluttransfusion*. By Privatdozent Dr. B. Breitner. Abhandlungen aus dem Gesamtgebiet der Medizin. Vienna: Julius Springer. 1926. (Med. 8vo, pp. 114; 24 figures. G.M.6.90.)

<sup>4</sup> *Dyspnoea*. By James Howard Means. Medicine Monographs. Vol. V. Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1924. (Med. 8vo, pp. 108; 22 figures. 11s. 6d.)

## PREPARATIONS AND APPLIANCES.

*Preparations for Cholecystography.*

The discovery by American workers that the gall bladder could be rendered visible to x rays by administration of tetra-iodo-phenolphthalein provided a valuable new method of diagnosis for use in disorders of the gall bladder. At first it was believed to be necessary to give the drug by intravenous injection, but it has since been discovered that almost equally satisfactory results can be obtained if it is given by mouth, provided that it is administered in a capsule, which protects it from the action of gastric juice. This represented a great simplification in technique, and the method is now firmly established in many hospitals.

The British Drug Houses have undertaken the manufacture of tetra-iodo-phenolphthalein and tetra-bromo-phenolphthalein. They supply these drugs in solid form, in solution for intravenous injection, and also in gluten-coated gelatin capsules for oral administration. The dose for intravenous administration is about 3.5 grams, and for oral administration 5 grams. The price of such doses is between 2s. and 3s.

## Nova et Vetera.

## DALTONISM AND THE ARTS.

In a leading article on colour-blindness in our issue of May 29th (p. 910) we commented on Part II of the Nettleship Memorial Volume of the *Treasury of Human Inheritance*, and Dr. Julia Bell's excellent work on this subject was commended as it deserved. Space forbade any digression into a consideration of the disabilities under which the subjects of dichromic vision suffer, but this branch of the subject is so interesting as to invite discussion, and especially as regards the obstacles which dichromism puts in the way of the painter. To this subject not much attention has been paid by medical writers, yet it is an interesting one.

In 1871 Dr. Liebreich noticed a strange-coloured picture in an exhibition in London. The subject of the picture which attracted his attention was a cattle market. The roofs of the houses and the oxen and cows were painted red in the light and green in the shadow, and from its peculiarities he inferred that the painter was a Daltonian—that is to say, that he suffered from defective sensitiveness for the colours red and green, and from that cause he used these colours in the place of the grey which to him was indistinguishable from red and green except by difference of illumination of the shades in question. Liebreich does not appear to have had an opportunity of verifying his diagnosis by examination of the painter's colour-vision, and it was not till 1903 that a paper was published by Professor Angelucci of Naples<sup>1</sup> in which a number of examples of colour-blindness in painters were cited, in whom the condition had been demonstrated by tests with Holmgren's wools.

Professor Angelucci found<sup>2</sup> that the peculiarity noticed by Liebreich was so constant in the works of Daltonians that he proposed to call it "*Liebreich's sign*," in honour of its discoverer. Not only did he detect and examine a number of Daltonian painters in Italy, but he formed a collection of paintings by those artists in whom he had established the fact of their defect by the usual tests. Some of these paintings were commissioned by him, and at the same time for comparison he had paintings from the same subjects executed by other painters whose colour sense was known to be normal. It appears probable from his account that some of his patients, if they may be so called, had defects of colour vision more extensive than mere Daltonism, but with this consideration he did not deal.

The diagnosis of Daltonism from the examination of a painting is made more difficult by the fact that after some years' experience its victims learn to know the names of the colours of many objects and employ pigments which are similarly labelled, but this resource is apt to fail in the case of a mixture of colours. One at least of Professor Angelucci's patients attempted to get over this difficulty by buying paints of blended tints ready made. But do what he will, it appears that the Daltonian cannot avoid making the mistake which constitutes Liebreich's sign. Pastel offers greater difficulties than oils, because the

crayons are not labelled with the names of their tints, and this much annoyed one of the artists who had to a great extent evaded his difficulties in oils in the way just indicated. The statement quoted in our leading article of May 29th that dichromic vision is frequently associated with perfectly normal vision for form confirms Dr. Angelucci's experience. Some of his cases would have been in the first rank of skilful technicians but for the quaintness of their colour schemes. Such artists are well advised to restrict their activities to black and white or monochrome.

A somewhat cursory survey of the 845 pictures in oil and water colours now on view at Burlington House did not afford a definite case of Liebreich's sign. To the mere physiologist who is not a painter or an art critic, a certain number of exhibits appear to be freakish as regards their colours, without betraying the definite stigmata of dichromism. Certain landscape painters appear to eschew contrasts of colours or even of shades to such an extent that some of them are obliged to emphasize the outlines of objects with lines of a deeper tint, with the result that the general effect is one of a coloured drawing. There seems no ground for accusing such painters of defective colour vision, for the low tones may be only the expression of the artist's preference; yet it is hardly possible to believe that the colours of a landscape in Spain or Italy are appreciated by them, as they are by most other persons. Some of these pictures give one the impression of having been painted during a partial eclipse of the sun. The use of green in the shadows, which Professor Angelucci associated with undue redness of the high lights, seems to be a favourite with some exhibitors. The subject, however, is a little complicated by the fact that some painters make use of special conventions to produce on the eye of the beholder the massed effect they desire. Thus in the white horses which are represented in the works exhibited by Mr. A. J. Munnings, R.A., bright grass-green is thus employed, and in one case sky-blue. The last picture is subdued and low in tone and contains scarcely any red, but the "*Gypsies*" on Epsom Downs and the Ascot pictures are full of bright colours. In No. 97 there is light green in the shadows of the King's face and in the Queen's hair, and the under surface of the black carriage front which is in shadow is painted with much green. Perhaps to the amateur eye the most surprising use of colour is seen in the front of the wheeler postilion's jacket in No. 405. Although in the bright light of the open sky, it is in shadow compared with the other side. Here the colours used on the gold-laced scarlet jacket are green, yellow, and (in the shaded arm) puce-purple.

We do not venture to criticize the use of these colours by an artist of Mr. Munnings's experience and distinction, but we mention it as an example of the wide differences which may exist between the impressions recorded by the eye of the painter and that of the man in the crowd. In No. 203 another artist has represented a scene containing much colour, but the linings of the monks' brown hoods, apparently intended to be white, are bright green, and the paper on which the hand of one rests is grass-green. There are a few other pictures in which light or bright green is used in the shadows, which need not be here specified.

In his summary Professor Angelucci says that most Daltonians learn how to distinguish red after long practice so that their faults with this colour are less visible, but it is otherwise with green. He thinks that an abuse of the colour violet also occurs. The completely dichromic use it largely in flesh tints, and those who are blind to the half-tones of red and green use it too much in the shadows. Green in the high lights is often rendered by yellow. An extravagant polychromatism is also characteristic of the Daltonian. The existence of so many dichromic painters in Italian art is explained, he says, by the fact that the colour vision of students was not tested. Had they been properly examined many of the pictures in his collection would not have existed. We have not heard of any such test in the schools of painting in this country. If the distinguished professor of anatomy to the Royal Academy of Arts were to examine the colour vision of the Academicians, Associates, and students of that august corporation the results might be interesting.

<sup>1</sup> Les Peintures des Daltoniens. Par le Prof. A. Angelucci, de Naples. *Revue d'ophtalmologie*, 3e série, 30e année, No. 12, Décembre, 1903, Paris, p. 1.

## GLASGOW UNIVERSITY COMMEMORATION.

## MACEWEN MEMORIAL.

The celebration of Commemoration Day at Glasgow University on June 23rd was marked by a series of notable ceremonies of medical interest. The chief features of these were the tributes paid to the memory of Sir William Macewen, who occupied the Regius Chair of Surgery for thirty-two years in Glasgow University. It had been originally intended that Professor Harvey Cushing should deliver an oration on the life and work of Sir William Macewen on this occasion, but unfortunately he found himself unable to visit these shores this year. In his absence Professor Archibald Young, successor to Sir William Macewen in the Regius chair, ably carried out the duty, giving in the course of his oration a sympathetically critical analysis of the character of Macewen as presented in his life and work, and offering warm homage to the work of his renowned predecessor and teacher.

## The Life and Work of Sir William Macewen.

Professor Young began with the statement that Macewen's life and Macewen's work were synonymous;

his life was his work, and his work was his life; throughout his life he seemed to have been actuated by the determination, perhaps hardly formulated in his mind but none the less implicit in his conduct, to devote his great powers unceasingly and without rest to making advance in orderly fashion along the line of progress. This was abundantly illustrated by the remarkable list of Macewen's published works, comprising over seventy separate contributions to the literature of surgery, the greater part of which was made up of papers and monographs of such importance and representing such a mass of scientific research and investigation as might have occupied the time and energy of several earnest workers. He referred more particularly to some of Macewen's larger works, which by their inherent merit, their scientific insight, and the irrefutable demonstration of their teaching, might be said to have established themselves as standard or classical presentations of the particular subjects with which they deal. His treatise on pyogenic diseases of the brain and spinal cord, and his works on osteotomy and on the growth of bone, ranked already as classics. His *Atlas of Head Sections* constituted a contribution to the surgical anatomy of the skull and brain which stood out as a permanent addition to scientific knowledge. This atlas was published in the same year as his great work on pyogenic diseases of brain and cord, only five years after the memorable address on the surgery of the brain and spinal cord which he delivered to the British Medical Association in Glasgow in 1888. During this period also Macewen published a number of notable papers in other departments of surgery, so that this must have been almost the busiest period in his life. In attempting to analyse Macewen's character as presented in his life and work, Professor Young made special reference to several traits which seemed to stand out with special clarity. The first was his infinite capacity for taking pains. No amount of trouble was too great if it meant the possible clearing up of a difficulty or the confirming of an observation. No detail of description, provided it was apposite, was ever wittingly omitted from a report or from an argument. Macewen was as meticulous in testing his tools as he was in verifying his facts. This was illustrated in his monograph on osteotomy and in his paper on chronic gut, its method of preparation and behaviour in

WILLIAM MACEWEN.

living tissues. A further trait was his faculty for taking full value out of every part of his work, in whatever line his energies were employed for the time. This was evident even in the earliest years of his medical life, when, in the course of his routine duties as police casualty surgeon in Glasgow, Macewen made observations on such minor problems as then presented themselves. Thus we have his observations on the diagnosis of alcoholic coma, and on wounds in relation to the instruments which produce them, and a further paper on penetrating wounds of thorax and abdomen. The latter probably had something to do with the direction of his thoughts towards the study of certain problems of thoracic surgery, which were to take more definite shape in the later years. These formed the subject of various papers from time to time, and there would appear to be almost a melancholy interest in the fact that what was probably his last published paper dealt with much the same subject, as in 1923, during his world tour on behalf of the British Medical Association, he delivered an address before the Australasian Medical Congress on the physics of the lungs and pleurae. A third trait in Macewen's character the lecturer referred to without offence as his self-sufficiency. He was not, and could not be, a "co-operator." He had confidence in his own powers, his own resources, and his own judgement. He did not readily accept the judgement of others, and seemed almost to cultivate a spirit of distrust of anything he had not himself put to the proof. Tradition meant little to him; surgical dogma he accepted only where and when his own judgement was convinced by his own observation and deduction. In his teaching of students he encouraged the same attitude of mind, and had much sympathy with what has been called "philosophic doubt." Neither team work nor the team spirit attracted him, but he had the faculty of getting the last ounce of work out of his assistant workers, because he gave the last ounce himself. Another

quality of Macewen's work was its thoroughness and completeness. He was never in a hurry to publish, and when he made his statement it was final. This note of finality was peculiar to much of his work and of his writing; it represented, in as perfect a form as he could give to the world, what was his final position at that stage, one more well set rung in the ladder of advancing knowledge. Macewen, however, would have been the last to claim in respect of any part of his work that it was possible ever to reach finality in research.

Three special aspects of Macewen's work were made the subject of special reference—his share in the development of modern aseptic surgery, his work upon bone, and his pioneer work upon the surgery of the brain and spinal cord. It had been said that Macewen was fortunate in having begun his work exactly at the right time, when "the possibilities of surgery were opening up like great tracts of undiscovered country," but it had also been added that "a genius such as his would have found undiscovered country to explore in any period." He played a great part in commending to his fellows the Listerian doctrine of wound infection and its prevention, and was from the first an ardent disciple of Lister, endeavouring to apply the Listerian doctrine in his work from the earliest period of his career. He, however, travelled farther than the master, and was one of the first to pass on to the development of what seemed to him the natural outcome of Lister's doctrines—namely, the ideal of asepsis and of

aseptic surgery. During the last twenty-five years of his life this was the ideal which pervaded his practice and teaching. In one sense he was fortunate beyond many of his fellows, and than most of the younger surgeons of later times, in that he was appointed a visiting surgeon with charge of wards in the Glasgow Royal Infirmary at the very early age of 29 years, when he was full of vigour and enthusiasm, when he had still the freshness of youth and something of its boldness, even of its daring. He played a large part in developing the practical application of Lister's doctrine, and soon his whole operative technique passed from the purely antiseptic to the aseptic. His reverence for Lister and his work remained with him throughout his life.

Professor Young proceeded to make more detailed reference to the work of Macewen. The surgery of bone constituted a large and important part, and probably was nearer his heart than any other of his scientific interests, for he seemed to have had his mind directed upon some aspect of it at nearly every stage of his professional career. His historic case, in which a new humeral diaphysis was built up step by step by a series of heteroplastic transplants, was first operated on by him as far back as 1878, and he was able to follow out the after-history of it for over thirty years. In his book on *The Growth of Bone*, published in 1912, he was able to give a comprehensive description of the process over that long period along with photographs showing the end-result of this great physiological experiment, and to give his conclusions with regard to the regeneration of bone. He was himself the great protagonist for the view that regeneration of bone was the property of the essential bone cell, especially the active or embryonal form of this, the osteoblast. This great and recurring controversy upon the role of the periosteum in bone regeneration was much with him, both in argument and experiment, through the greater part of his active life. His work on bone, however, found a more useful field of application in the surgical treatment of bony deformities. He set himself the problem of devising some method of dealing with the deformities associated with rickets, a disease which was particularly prevalent in Glasgow. This culminated in his work on osteotomy, which was a personal triumph, and Macewen's operation of supracondylar osteotomy ere long became the operation of universal choice for the correction of genu valgum. For the other deformities suitable operations were devised. It was of interest that he also discussed the causation of the malady which led to these deformities, and though his views on the etiology of rickets did not necessarily deal with, or even foreshadow, the more modern views on the biochemical and other agencies to which many now ascribed its production, yet his conclusions as to the influence of bad hygiene, the want of pure air, the absence of sunshine, the effects of chronic ailments, and perhaps of epidemic diseases acting during the growth period, were still worthy of acceptance even in the light of modern knowledge.

Macewen, however, probably achieved his greatest fame as the pioneer of brain surgery. His address in 1888 to the British Medical Association in Glasgow has become historic, and created a sensation throughout the world as "one of the most remarkable contributions to surgical literature which the present day has produced." Thirty-four years later, when the Association again met in Glasgow in 1922, Macewen, now its President, took as his subject of address practically the same theme, its title being "Brain surgery." This was in fact a masterly survey of his own work during that period, of the more recent developments in brain surgery, and also of the great possibilities of the future. Great as was Macewen's work on the surgery of brain tumours and their localization, it was probably true to say that he stood out more clearly as the pioneer in the diagnosis and surgical treatment of intracranial suppurative conditions. His association with the late Dr. Thomas Barr of Glasgow in this work was one of the most fortunate and fruitful associations in the history of modern surgery, as it led to the laying of the groundwork of most of our present-day procedure in the operative treatment of intracranial abscess, meningitis, and sinus thrombosis.

Of Macewen's powers as an operator the lecturer spoke

briefly. It could not be claimed that he was an operator of heaven-born genius, or that he was gifted with exceptional manual dexterity. He was, indeed, slower than many surgeons of his day, but he seldom troubled himself about the matter of time. As Patrick had said, "He aimed at thoroughness rather than speed and dexterity." It was probably true to say that in certain branches of surgery Macewen had less than the average facility, and less than the average success, but in those branches of the art which he had done so much to advance, and in which he was the unrivalled master, he was *facile princeps*.

The greater part of Macewen's active work of investigation had been carried out prior to his appointment to the Regius chair in the University. What might be called his creative period had been passed before he turned his mind to the duties of a university professor, but he continued to the end imbued with the spirit of research, though he turned his mind definitely and seriously to the duties of teaching. He was successful in making a deep impression on the teaching of surgery in Glasgow, an impression whose influence was felt far beyond the University. His principle of instruction was to make the student of surgery think for himself, and his métier was as a clinical teacher. His ambition was to establish a great clinical school like that of Kocher of Berne, whose method of teaching was strikingly similar. Macewen always put his professorial duties first and spent much time and energy in preparation. He had strong opinions as to the proper method of training the young surgeon, and opposed strongly any attempt to graft the English tradition in teaching upon that in force in Glasgow. He eventually succeeded in obtaining the institution of a well equipped department for the prosecution of the practical part of his operative surgery course, as well as for the purposes of research.

Macewen (Professor Archibald Young concluded) was a great man—one of the world's great men—but, like many great men, he was not without the defects of his qualities. He earned respect, he excited admiration, in virtue of his energy, his industry, his originality of thought, his brilliant research. He kindled in his students and assistants something of the spirit of investigation with which he was himself so richly endowed, but it was extremely doubtful if he ever could be said to have gained, or even if he ever desired to gain, the affection of those who were his most loyal helpers. But these defects served only to bring into more marked relief the greater qualities of the man whose genius was dedicated for so long to the service of Glasgow University, and of the great surgical school of which Glasgow is proud. Truly, in the possession of Macewen this university and this city had one whose fame was world-wide. His clinic was visited by surgeons from all the world, and at one time, indeed, he was almost better known abroad than at home. Abroad his name was one to conjure with, and on more occasions than one he was strongly invited and urged to accept appointments elsewhere; but though all kinds of lures were held out to him he declined, and persisted in his decision to remain in Glasgow. Surely the loss of others was Glasgow's gain. "We remember with gratitude the life and work of Sir William Macewen. The fruits of his work are with us."

#### Presentation of the Bust.

Dr. FREELAND FERGUS, the chairman of the Memorial Committee, in asking the Vice-Chancellor (Sir Donald MacAlister) to accept custody of a bust of Sir William Macewen on behalf of the University, said that in response to an appeal issued by a committee which had been formed for the purpose of perpetuating Sir William Macewen's memory in Glasgow a considerable sum of money had been obtained. It had been determined that the money should be applied to three purposes. In the first place, it was decided to procure a bust of Sir William Macewen for presentation to the University, and it was specially desired that this should be placed where it would be seen by future generations of medical students. Secondly, the committee determined that a replica of the bust should be presented to Lady Macewen. Thirdly, the committee had decided that the remainder of the money should be applied to

## EMPLOYMENT FOR THE TUBERCULOUS.

[THE BRITISH  
MEDICAL JOURNAL]

the foundation of a Macewen Memorial Lectureship, and arrangements had been made with the University Court to carry out that purpose. Sir DONALD MACALISTER, in accepting custody of the bust (the work of Mr. G. H. Paulin, A.R.S.A.), said that it was a memorial of a great investigator and a great teacher, whose achievements in the beneficent science and art of surgery had enhanced the fame of the Glasgow School of Medicine and had added lustre to the chair once occupied by Lister. He offered the cordial thanks of the University to the pupils and admirers who had enriched the University with this and other cherished memorials of Sir William Macewen.

Among the recipients of the honorary degree of LL.D. at the graduation ceremony were Professor Tuffier, the well known French surgeon, and Dr. A. K. Chalmers, for many years medical officer of health for the city of Glasgow. Various bequests to the Medical Faculty of the University were intimated: from the late Dr. John Hall and his sister Miss Helen Nelson Hall, London, the sum of about £70,000, for the foundation of Tutorial Fellowships in Surgery, Medicine, and Midwifery; from an anonymous donor, £30,000, for the foundation of a Medical Research Fund; also from an anonymous donor, £5,000, for the foundation of a Royal Samaritan Hospital Lectureship in Gynaecology.

## EMPLOYMENT FOR THE TUBERCULOUS.

SOME light is thrown on the difficult question of the employment of consumptives when they have reached the stage of apparent recovery by three documents which have recently come into our hands. It will be profitable to give some account of them.

In October, 1924, the Joint Tuberculosis Council appointed a subcommittee to undertake a comprehensive survey of the question of the employment of consumptives. The subcommittee reported last March. On May 12th of this year the committee of management of the Cambridge-shire Tuberculosis Colony at Papworth presented its report for 1925. And Dr. Bolton Tomson, vice-chairman of the Hastings Tuberculosis Care Committee, has just published a small book entitled *Notes and Suggestions on the Finding of Employment for the Tuberculous by Tuberculosis Care Committees*.<sup>1</sup>

Taking the last of these productions first, it may be noted that Dr. Tomson thinks the problem of finding employment for the consumptive is best solved by permanent colonies, such as that at Papworth, and although, in his words, "conclusions that are self-evident to the expert and the initiated often take long to obtain a general acceptance," it is, perhaps, more than possible that the community will have to shoulder the expense of a colony system. In the meantime Dr. Tomson sets forth the difficulties which care committees have to face, and describes three forms of occupation which can be usefully developed in suitable cases. The difficulties met with in the patients arise in deciding on their physical capacity for work, on their character and their willingness to work if help is granted, on their special aptitude for different kinds of occupation, and on their general education. The man who has occupied a good position, and has exhausted all his savings through the long duration of his disease, is generally a highly satisfactory patient to help. On the other hand, there are few employers who will engage a tuberculous person. Hence most of the sufferers must work on their own account. They should also be at liberty to work when they can and rest when they ought. A further difficulty noted by Dr. Tomson arises from "disablement benefit" under the National Health Insurance Act, 1924. The author thinks that it would be an enormous advantage if those partially disabled permanently from tuberculosis were allowed to do what work they could, and still receive their weekly payment provided their earnings did not exceed a specified sum. To Dr. Tomson tuberculous persons are a class apart, and to make an exception for them would not establish a precedent. Without payment for work many patients lack the incentive to try what they

can do; they mope about at home, and invariably go downhill. For the man who is not bound by Insurance Act restrictions, and is able and willing to work, Dr. Tomson at once accepts the proposition that a subsidy is required, and that this subsidy must come from the Government. The author then gives details of the three schemes for providing work which he would recommend to care committees. For women he suggests the unpicking and scouring of old woollen or silken hand-made garments, the materials of which can then be made up into fresh garments suitable for the poor. He has found that this employment, though not very lucrative, competes easily with the hard work of charring, and is far more remunerative than home needlework. For men Dr. Tomson suggests rabbit farming and the utilization of waste products, such as old clothes, pigswill from neighbouring houses, and so on. By this utilization the industry is subsidized and can be made profitable. In each case there is a certain and constant sale for the products. But it is necessary in these employments, as in all others, to select persons who are suitable for the job. Dr. Tomson gives interesting details of the materials required and their cost in each of these occupations.

The employment subcommittee of the Joint Tuberculosis Council consisted of Dr. Jane Walker of London, Dr. D. P. Sutherland of Manchester, Dr. H. Vallow of Bradford, and Dr. J. B. McDougall of Hexham (convener). Their report is not a model of clarity. This is probably due to the intricacies of the subject; to the distances which separated the members, and the consequent difficulty they had in meeting; and to the fact that they were not agreed in opinion. The subcommittee investigated eight schemes by which it has been attempted to find employment on an organized industrial basis for consumptive persons. It seems that under these schemes 419 ex-patients, apart from those employed at institutions as nurses, maids, porters, and so on, are now engaged in employment as wage-earners. The subcommittee was convinced of the success of the employment of ex-patients as full-time workers on the staffs of sanatoriums, and no further reference need be made to this class of worker. The concern of the report is with those ex-patients who, having been patched up at a sanatorium, and put through a course of training in work more suitable for their condition than their original occupation, are then in need of remunerative employment. It is stated in the report that at none of the training colonies inaugurated by the Ministry of Health has any serious attempt been made to continue the work at a settlement or on a proper industrial basis. The schemes for this purpose have been private, voluntary or charitable in origin.

The subcommittee was of opinion that schemes for the employment of the tuberculous should have three objects: (1) occupational therapy, (2) vocational training, (3) permanent settlement of ex-patients who had passed through a satisfactory period of training. Dr. Vallow, however, dissented, for he does not believe that the majority of patients would accept these provisions, or that they are financially possible. (The reasons for his belief are not given in his supplementary report.) The subcommittee thought that training colonies and settlements should not be started *de novo*, but that occupational therapy should be begun at a sanatorium, and the departments developed slowly at first. The training should be an integral part of treatment, until by co-operation and efficiency a surplus of permanent settler after another. The raising of any large sum as capital should be delayed as long as possible. Occupational therapy should be directed towards permanent employment; the occupations should not be too numerous, and should be those in which there was an assured market; and the work should be repetitive, as in mass production, rather than highly skilled. In such occupations the period of training could be reduced to a minimum, and the difficulties raised by the question of giving a bonus to those under training ("trainees"—a horrible word—in the report) would be lessened. The subcommittee was of opinion that in forming a settlement the venture should at once be legalized by making it a limited liability company. There should be a small committee of

<sup>1</sup> *Notes and Suggestions on the Finding of Employment for the Tuberculous by Tuberculosis Care Committees*. By Dr. Bolton Tomson, M.D. London: Baillière, Tindall and Cox. 1926. (Demy 8vo, pp. 27; 3 figures. 1s. net.)

management, with a suitable and enthusiastic director, who in most cases should be a medical man, and should have the largest amount possible of freedom of action. Under him there should be "key" men in the various industries, who should be employed in their original occupations, and, whenever possible, should themselves have been sanatorium patients. Patients should be housed in hostels, and later, as the trading became established, houses should be built for married ex-patients and their families. The provision of such houses, which would cost at least £450 each, might come within the scope of the local council. In the matter of finance the subcommittee drew a distinction between overhead charges and maintenance and wages. The object should be to pay maintenance and wages out of the trading account, whereas the overhead charges should come from another source. Two members of the subcommittee thought that capital should be obtained through voluntary contributions to a central fund; the other two were of opinion that it was the duty of the State or of the local authority to provide employment schemes. It was suggested, also, that as the work was really a kind of treatment, the Ministry of Health should take a share by defraying the cost of maintenance of the employees on an agreed rate. The majority of the subcommittee did not favour this suggestion. The salaries of the medical director and of non-tuberculous instructors should be overhead charges. On the question of the payment of wages and maintenance out of the trading account, various difficulties were found to exist. Thus the subcommittee favoured the use of the permanent settlements for vocational training, and also, possibly, for occupational therapy. But as such labour could not be paid at ordinary wages rates, it became of the nature of subsidized labour so far as the settlement was concerned. Such subsidized labour was stated to be necessary to the success of the settlement, and in many cases the persons under training were paid a bonus. The question arose whether the bonus should be paid in cash after a maintenance charge had been deducted, or should all profits go to the settlement? The subcommittee was of opinion that, whatever the answer, the State should pay a bonus to those whose training extended over a long period. For the trained settlers the rate of wages, if not fixed by trade unions, must be sufficient to enable the ex-patient and his dependants to live in comfort.

As the occupations selected for the settlement must come into competition with business concerns, two of the first conditions of success were found by the subcommittee to be businesslike administration, with successful advertising capacity, and ready markets. Even if these conditions were fulfilled two further difficulties arose. The patients drawn from an area with a suitable market might be quite unsuitable for the occupations selected. Thus the coal-miner had been found to be a very difficult person to fit into an occupation suitable for his working capacity as an ex-patient. Farm work proved to be too arduous in most cases, and it was not always easy to fit ex-patients in these categories with an occupation. In fact, the director of the New York Tuberculosis Association considered that "teaching Chinese to a negro, infusing a Latin-American with a puritanical outlook on life, or inducing statesmanship in a politician are problems equal in toughness to finding a suitable job for a tuberculous person, and keeping that person in that job." The other difficulty arose from the trade unions; but the unions had, after a clearing of the air, pronounced the following decree: "Labour has no objection to the employment of consumptives in colonies provided that certain stipulations which are all 'labour protecting' are agreed to. What it does object to is the possibility that consumptives may be trained and then thrown on the labour market, there to obtain work for which a reduced rate may be paid by unscrupulous employers. Provided the man is employed in a colony and paid the current wage, and the produce not sold at undercut prices in the open market, no objection is raised."

From the rest of the subcommittee's report we gather that the aim of the settlement worker is mainly to obtain additional remuneration, though he is not altogether unmindful of the benefit that accrues to his health; that he is liable to estimate the value of his work in hours rather

than in market value; that the "civilian" married ex-patient with a large family is a great difficulty, but that the ex-service pensioner introduces the problem of the rate of wages that should be paid to him; and that the expectation of life in a settlement is two or three times longer than it is with sanatorium ex-patients. In defence of the cost of establishing settlements the subcommittee urges that the system removes infectious persons from direct contact with the rest of the community; that it enables the maximum productive capacity of the ex-patient to be determined; and that in any case the results are cheaper than frequently admitting into, and discharging from, a sanatorium a tuberculous patient who returns to his own home and work.

The report of the committee of management of the Cambridgeshire Tuberculosis Colony at Papworth is somewhat of a hymn of praise in honour of the ten years' success of the venture. The committee and the medical director, Dr. P. C. Varrier-Jones, have, in truth, much upon which to congratulate themselves. The twenty-five houses, for which a grant of £10,000 was received from the Ministry of Health, are now complete. But they cost more than the Ministry allowed, so that £1,000 had to be found elsewhere. The inhabitants of the institution and village now number 559, including 90 healthy children. A show-room for the sale of furniture has been opened in Cambridge. The enthusiasm of the medical director is abundantly displayed in his portion of the report. "So far as Papworth is concerned, we were not only on the right lines, but our faith has been completely justified." If a village settlement is composed of men "who are prepared to give more than they get," and not of "those who want to get more than they give," "then all will be well." Dr. Varrier-Jones thinks that village settlements are essential in combating tuberculosis; and he enumerates the ideal principles necessary for success. Some experimental medical work has been carried on during the year. Thus trial was given to sanocrysin, but the conclusion was that it had no effect whatever in checking the disease. On the trading side the sound principle has been adopted that the industries are a commercial concern, and trading on "sympathy" is avoided. The social side and the amusements of the settlement are well organized, and the development of the scheme has plainly been very satisfactory. On Monday last His Majesty paid a visit of inspection to the colony.

### EPSOM COLLEGE.

THE annual general meeting of the Governors of Epsom College was held on June 25th, when the chairman of council, Dr. RAYMOND CRAWFORD, presided. A vote of condolence was passed with the relatives of the late Sir Henry Morris, Bt., who, in 1924, resigned the position of treasurer which he had held for eighteen years.

THE CHAIRMAN expressed his satisfaction that in the near future there would be representatives of the British Medical Association and the Medical Insurance Agency upon the council of the College. He submitted the annual report of the council, which showed a substantial financial surplus on the year's working; this gratifying result was due to the receipt of several legacies for general purposes and to the zealous support of many old and new friends of the College. The thanks of the governors were due to the honorary local secretaries, the British Medical Association, the Medical Insurance Agency, the Pathological Society of Great Britain and Ireland, the numerous Panel Committees, and the Editors of the *British Medical Journal* and the *Lancet*. The various improvements at the College during the year included the erection of a new chemistry block at a cost of about £10,000, which would be complete and in working order by the end of July; a lower school annexe, costing about £2,500, and providing much needed washing and drying room accommodation; and the reorganization of the heating and hot-water systems at the College, involving an expenditure of about £6,000, but ensuring a considerable annual saving. A committee had been appointed to consider the construction of a more suitable cricket pavilion, at an expenditure of about £2,500, but

it was felt that the council would not be justified in devoting money from the general funds of the College for this purpose owing to the very large sum expended on other improvements. If the committee was able to raise enough money it was hoped also to take in hand the much needed levelling of portions of the playing fields. Mr. Herbert S. Pendlebury, who had held the appointment of treasurer since 1924, resigned this office, and in his place Sir William Hale-White was appointed. The War Memorial Fund, which had been instituted by the Old Epsomian Club to enable the nave of the chapel to be rebuilt in harmony with the new chancel, would be closed at the end of the present year. The total cost of enlargement, fixtures, and furniture was about £11,500, and at present there was a deficit of nearly £2,000. A new scholarship had been provided under the will of the late Dr. James Taylor to assist the education of any specially meritorious pupil at the College, and a new annuity had been bequeathed by Miss Mary Elizabeth Dunn. The school library had been completely refurnished and redecorated and adequately equipped.

#### *Pensions and Scholarships.*

The scrutineers, Dr. Seymour Taylor, Dr. E. Climson Greenwood, and Sir Ernest Goodhart, reported the successful candidates to be as under:

| <i>Pensionerships:</i>  | Votes. |

## THE HEALTH OF THE NAVY.

### REPORT FOR THE YEAR 1923.

THE statistical report of the health of the Navy for the year 1923 has just been published. It is similar to the report for 1922, of which a notice appeared in the BRITISH MEDICAL JOURNAL in September last (p. 523), and contains no features or record of incidents of an outstanding character. Its merit lies in the fact that it presents accurate statistical data for comparison with previous years and with the other services. Continuity of statistics is what it aims at, and rightly so.

#### *Incidence of Sickness.*

The average strength of the Royal Navy for the year under review was 89,100, and of this number 35,650 were on the Home Stations, 23,850 in the Atlantic Fleet, 16,740 on the Mediterranean Station, 1,990 on the North America and West Indies Station, 4,730 on the China Station, 1,740 on the East India Station, 1,570 on the Africa Station, and 2,830 on the Irregular List—that is to say, crews of warships on passage to and from foreign stations, Imperial personnel lent to the Australian Navy, and crews of the New Zealand Division. The returns of sickness and injury from all of these show a marked improvement in the general health of the Fleet. The total number of admissions to the sick list for disease or injury was 42,186, or 473.46 per 1,000 of the average strength, a decrease of 98.57 per 1,000 on the average for the previous two years, and of 85.56 on the rate in 1922. The majority of the admissions were due to venereal diseases (8,295), diseases of the respiratory

system (5,162), of the digestive system (6,662), of the areolar tissue and skin (5,566), and to local injuries (7,986). No other disease or group of diseases exceeded 1,000, and there was a marked freedom from the enteric fevers and Mediterranean fever, which previous to the year 1907, when the use of goat's milk and unboiled fresh milk was prohibited in the Navy, was a source of considerable inefficiency. Sandfly fever, on the other hand, shows no signs of decrease. There was a marked improvement in the incidence of influenza, only 863 cases being recorded, as compared with 4,514 in 1922. Prophylactic influenza vaccine, prepared at the Royal Naval Medical School, Greenwich, was used, inoculation being entirely voluntary, in addition to other preventive measures. The healthiest station was the Atlantic Fleet, with a ratio of 360.62 admissions per 1,000; the most unhealthy the East Indies, with 870.11, and China with 868.07 per 1,000. The ratio on the Africa Station was 659.86 per 1,000; on all other stations it was between 400 and 500 per 1,000.

#### *Invaliding.*

The ratio of invaliding out of the service was 16.03 per 1,000, or 5.79 less than the previous two years' average and 4.23 less than in 1922. In only one station—Africa—was there an increase on the two-year average, a slight one of 2.97; in all others the decrease in the ratio of invaliding varied from 2.29 on the China Station to 9.09 in the East Indies. In a table showing invaliding according to age and length of service the majority, 479 out of 1,511, belonged to the age group 25 to 35; and 605 to the group 5 to 10 years of service; but these figures are of little value without information as to the strengths of the various groups. The chief causes of invaliding were: diseases of the eye, 203 cases; of the ear, 166; gonococcal infection sequelae, 156; tuberculosis, 150; and neurasthenia, 103 cases.

#### *Mortality.*

The total number of deaths in 1923 was 194, equal to a ratio of 2.17 per 1,000. This is 1.35 less than the previous two years' average, and 1.27 less than in 1922. The deaths from disease numbered 125, and from injury 69. The decrease in mortality was general on all stations, being as much as 3.50 per 1,000 less than the two years' average in the East Indies and 3.49 per 1,000 less on the North America and West Indies Station. In the 1922 report a table was given showing the yearly death rates from 1856 onwards. The table is repeated in the report under review, and shows that 1923 has had the lowest death rate on record—2.17 from all causes and 1.40 from diseases alone. A chart showing the fluctuations and eventual remarkable decline in the death rates during the last half-century would be a significant demonstration of the improvement in the health conditions in the Royal Navy. Unfortunately no graphic charts are introduced into these reports.

#### *Comparative Statistics.*

Now that the report of the health of the Royal Navy for 1923 has been published a comparison can be made between it and the health of the Army and Air Force, the reports on which for the same year were published at a considerably earlier period. The following table may consequently be of interest as showing how far the main health statistics of the three forces resemble one another.

| 19 3.                        | Navy.  | Army. | Air Force. |
|------------------------------|--------|-------|------------|
| Admission rate per 1,000 ... | 473.46 | 484.0 | 473.8      |
| Invaliding ... ..            | 15.03  | 14.50 | 12.7       |
| Constantly sick ... ..       | 21.84  | 41.52 | 23.0       |
| Deaths ... ..                | 2.17   | 2.84  | 3.9        |

These figures are not, however, altogether comparable, as the admission rate in the army excludes officers and the constantly sick includes men treated as out-patients. The R.A.F. constantly sick and admission rates exclude men with less than forty-eight hours' sickness.

The report has also a table of the health statistics of the Royal Marines at headquarters. The strength was 3,710, the admissions 784.09 per 1,000, the invaliding 21.02, and the mortality 3.23 per 1,000.

## THE PROBLEM OF RHEUMATIC INFECTION IN CHILDREN.

### THE ASSOCIATION'S REPORT.

As it exists in this country to-day, rheumatic infection is one of the great infective diseases afflicting the children of the poorer classes. In the harm that it produces it is comparable only with such infections as tuberculosis and pneumonia. Meeting with it here on the grand scale, the British school of medicine has been responsible for most of the important researches into the disease. The foundations were well laid by W. B. Cheadle in his lectures on the rheumatic state in childhood, given in 1888, and since then there has been continuous effort on the part of British physicians to advance against the difficulties of this national problem. It is probably true to say that in no other of the major diseases of childhood has so great a proportion of valuable research been carried out by British workers; and when the special prevalence of the disease in this country is considered it is difficult to escape the thought that the problem of rheumatic infection is one specially set the British medical profession to solve. It is, therefore, with particular pleasure that we devote this week's SUPPLEMENT to the Report of a Special Subcommittee of Inquiry into Rheumatic Heart Disease in Children.

This inquiry owes its inception to the Section of Medicine at the Annual Meeting of the British Medical Association at Portsmouth in 1923. In opening a discussion on the "Etiology and treatment of heart disease in early life," Dr. Reginald Miller referred to the various gaps in our knowledge which prevented our combating in a national way this great national disease. In particular he laid stress upon the fact that—such was our ignorance of the factors in the mass production of the disease in England—we were making, and could make, no organized effort to diminish the prevalence of the infection; yet there was one indisputable but unexplained fact—the class-incidence of the disease—which was likely to throw great light upon this very question, were it looked into. He therefore suggested that a small committee should be appointed to investigate the environmental factors in the production of rheumatism, urging that the possibility of damp houses breeding the disease should be examined.

In taking this line Dr. Miller was doubtless giving expression to what was in the minds of many others, and on the motion of Dr. George A. Allan a resolution was carried asking the Council of the Association to appoint such a committee. The matter was referred by the Council to the Science Committee, which in January, 1924, appointed a Subcommittee "to inquire into the steps which have been, and are being, taken in relation to the prevention, detection, and treatment of cardiac disease in children, and to make proposals in connexion therewith."

Sir Humphry Rolleston consented to act as Chairman of the Subcommittee, and we may here express the Association's gratitude to him. The fact that, amid the many duties of his then office as President of the Royal College of Physicians, he undertook this extra work, gives public emphasis to the importance of the subject under inquiry. The Science Committee

was also fortunate in securing the services of Dr. F. J. Poynton, whose pioneer work in rheumatic infection is so well known. Dr. George A. Allan of Glasgow, Dr. Carey Coombs of Bristol, and Dr. A. P. Thomson of Birmingham were also appointed. Their special interest in the rheumatic problem in these cities enabled the Subcommittee to gather valuable information over a wide field. Dr. Reginald Miller was appointed Honorary Secretary. Sir Thomas Lewis was unable to accept membership of the Subcommittee, but at the invitation of the Chairman gave much appreciated help by attending its meetings.

The point of view of the Subcommittee was, therefore, essentially that of the clinical physician. Although the Report deals with certain aspects of rheumatism which are outside the strictly clinical purview, and much of it must appeal specially to public health workers, yet we regard it as a gain that it is written by those who are themselves actually responsible for the medical treatment and welfare of numbers of rheumatic children. The Preface to the Report is a brief document summarizing the conclusions and proposals of the Subcommittee as a body. The four reports, upon which the Preface is based, are written by the individual members, who are alone responsible for them.

### *Environmental Influences.*

In some respects the first report, which is on the environmental and other predisposing causes of rheumatic infection, is the most important of the four, in that it deals with matters which may lead towards the prevention of the disease. In it Dr. Miller follows up the line of thought of his Portsmouth paper from which we have already quoted. There he said that rheumatic infection was almost entirely a disease of hospital as opposed to private practice; but later work, done in Bath and Birmingham particularly, shows that the class-incidence of the disease is indeed unlike that of any other non-infectious disease. There seems to be a definite rheumatic stratum of society, excluding the well-to-do on the one hand, and, though not so completely, the very poor and semi-destitute on the other. Further, it appears true that it is a disease of towns, especially of industrial towns, rather than of rural districts, and some startling figures are quoted in this connexion. The rheumatic infection is therefore essentially a disease of the children of the artisan or upper poor classes, particularly of those living in industrialized areas. To come back to the question asked at Portsmouth—What is the explanation of this peculiar fact? Tonsillar disease is too widespread to explain it. Living on low-lying sites or near water will not of itself account for it, as witness Dr. W. Attlee's most important experience at Eton College. Attendance at elementary schools, with its resultant exposure to bad weather and epidemics, is, taken alone, inadequate, or rural children would suffer most. Dr. Miller concludes that it is largely a matter of living in damp houses, especially in basements and in ground-floor rooms with no cellars beneath them. Investigations carefully pursued in London, Bath, Birmingham, and Bristol all tell much the same tale—namely, that nearly two-thirds of the children, when first attacked by rheumatic infection, are living in damp rooms. The Subcommittee concludes that this fact has a very important bearing on the problem of the prevalence of rheumatic infection in this country.

### *Bacteriology of Rheumatic Infection.*

Still with the prevention of the disease in mind, the Subcommittee has in Part II applied itself to this question, and the report written by Dr. Carey Coombs

and Dr. F. J. Poynton will be read with interest. It is now over a quarter of a century since Dr. Poynton and Dr. A. Paine advanced the view that the infective agent was a streptococcus. In spite of many failures and difficulties it appears that this view is steadily, though slowly, gaining acceptance. Recent investigations, says the Report, go to support it. It seems likely that the time is approaching when judgement in favour of the streptococcus theory may be given by default—no claimant remaining against it. Even so, so much remains which is obscure that we hope that the centre of activity in rheumatic bacteriological research will not shift away from this country.

#### *The Effect of Tonsillectomy.*

With Part III the Report begins to deal more directly with the treatment of rheumatic infection in children. The effect of tonsillectomy has been studied by others, but their results have been in total disagreement. Dr. Miller, who writes this section, suggests that this is due to their use of a method of investigation which, in this protean disease, is too complicated to give accurate results. Instead of attempting an investigation by a "follow-up" method, he advises the study of a series of cases of active rheumatism in tonsillectomized children, and a comparison of such with that seen in children with unremoved infected tonsils. Applying this method to a series of cases, he finds evidence that the infection is definitely modified by the operation, the heart in particular tending to be spared. No protection seems to be given against chorea, but the outlook as regards carditis is, of course, of prime importance. Figures relating to active rheumatic infection in children whose tonsils have been completely removed can be compiled with fair ease, and it will be interesting to see if the results of the present series are confirmed by others. Proceeding a step further, the Subcommittee has had to face the question of the advisability of tonsillectomy as a routine measure in rheumatic children. The opinion expressed is that to recommend such a step at the present time would be premature; the presumption is, therefore, that with growing opportunity for expert surgical assistance early tonsillectomy should be widely adopted. The Subcommittee has wisely refrained from discussing the different modes of operation, and has referred simply to the "complete removal" of the tonsils.

#### *Organized After-Care.*

Dr. George A. Allan, writing in co-operation with Dr. A. P. Thomson, furnishes an interesting report on what is being done to provide efficient after-care for rheumatic children. Evidently where such facilities are provided the results are encouraging. Although it appears that interest in this work is increasing, the burthen of the report is that it is as yet quite insufficient.

#### *Conclusions and Proposals.*

The proposals of the Subcommittee are succinctly expressed in the Preface, and more fully in the four reports. We will here deal only with the two which are of greatest importance, and which call for a widely organized effort.

First, in the all-important matter of prevention, there is small satisfaction to be obtained from the Subcommittee's expression of opinion that, up to the present, little or no organized effort has been made to prevent the disease. When we consider that, in its prevalence and harmfulness among children, it equals, if it does not surpass, tuberculosis itself, we may well wonder what the public will think of this verdict. The

class incidence of the infection seems to point clearly to the importance of environment in spreading the disease, and this should be susceptible of control. It is for the public health authorities to investigate and to act. It is not enough to say in this connexion that "dampness in houses is a condition which stands condemned, as a result of general experience and in relation to various ailments in addition to rheumatism."<sup>1</sup> Were this so, it is a singular excuse for the damp house; but the Association's report suggests that damp produces acute rheumatism in children in a way more direct than by increasing the general sickness rate. The nation may surely desire some assurance that the new homes of the people will be in this respect an improvement on the old. As regards exposure to wet by attendance at elementary schools, it is clearly an immense undertaking to provide drying facilities for the children, although we believe that in isolated instances such are being established. But it would not be a difficult matter to arrange that, on a single medical certificate, a rheumatic child might for some months be allowed to attend school irregularly even though it cannot yet be classed as "physically defective."

Secondly, there is the question of the provision of prolonged treatment for children with rheumatic heart disease. The need is for more beds where these children can have controlled rest with education. It is their education and the education grant which have proved such difficulties in the past. The movement to provide proper provision for these cases is increasing; it needs organization and guidance. In this connexion we would offer some suggestions. First, these cases are a confession of failure: it is prevention that must be the prime object of our efforts. Secondly, every case of heart disease in a child is essentially a rheumatic rather than a cardiac problem. It belongs to the realm of pediatrics rather than to that of cardiology. Therefore, thirdly, it is essential that these recovery facilities should be worked in close co-operation with the hospitals. In saying this we are but restating the opinion of the combined meeting of the Children's and Public Health Sections at the Association's meeting at Bath last year, where this matter was under discussion.<sup>2</sup> There a strong feeling was expressed against the proposal to set up "cardiac clinics" and "cardiac experts" on the lines of the present antituberculosis movement. Lastly, we suggest that caution is necessary before it is regarded as settled that open-air treatment is wisest for rheumatic children. It is but a short step from overexposure to active rheumatism, probably shorter than obtains in tuberculosis, and the results of open-air schools and other treatment of the same type seem hardly uniform enough to justify as yet the adoption of this mode of treatment as a settled policy.

### SCLEREMA NEONATORUM.

Sclerema neonatorum is a disease both rare and remarkable. It appears first in medical writings in terse and graphic Latin, "foetus vivus, frigidus et rigidus," as recorded by Usembezius of Ulm in 1718. But it was Underwood of the London Lying-in Hospital who in 1770 gave the first good clinical description of the condition. And it is again from London that, in the two recent numbers of the *Archives of Disease in Childhood*, there has appeared a really important contribution to the subject by

# THE EPILEPSIES.

JULY 31, 1926]

Harrison and McNee.<sup>1</sup> Between 1770 and 1926 nothing very substantial has been added to our knowledge of the subject. Parrot simplified the confusion of the nomenclature by differentiating sclerema and oedema neonatorum (1877); yet there still remain with us such confusing and ambiguous terms as pseudo-sclerema and scleroedema. There has also been a good deal of hard guessing at the cause of the disease: beginning with Usembezius, whose theory was that the mother during her pregnancy had gazed much at the statues of the saints, and so had impressed their rigid pose on her infant; the theory of a deficiency of olein in the subcutaneous fat and the raising of its melting point, advanced by Langer (1881); a tropho-neurosis depending on disorder of the heat-regulating centres, the view of Italian writers and supported by Ballantyne; the theory of infection, also put forward in Italy, and in England by Eustace Smith; the theory of disorder of metabolism and of internal secretion.

Hitherto advance in knowledge has been hindered by the lack of two things—an agreed definition of the clinical features of the disease, and accurate microscopic and chemical examination of the morbid tissues. It has been the custom to exclude cases of so-called pseudo-sclerema, but the cases of recovered sclerema reported by Carpenter, Garrod, and Paterson are now generally accepted as cases of true sclerema. Harrison and McNee present five cases of this milder group; four were fatal and one recovered; the second of their cases they themselves admit to be doubtful. They take up and attack the problem of sclerema from the side of histology and chemistry, presenting a careful examination of the morbid subcutaneous tissues by modern chemical and microscopic methods, with control observations on normal fat in young infants.

Paraffin and frozen sections showed definite thickening of the interlobular fibrous trabeculae; atrophy and necrosis of fat cells; and a remarkable deposit of acicular crystals within the cells, also thickly encircling them "like the cover of a ball," and even deposited in thick masses, which appeared as empty clefts in the paraffin sections. There was observed also in the sections definite obliterative endarteritis; an abundant deposit of lime salts in most of the cases; giant cells adjoining the crystalline deposits; and some round-cell infiltration throughout. In all cases the true skin was unaffected; in the most severe case the process of fibrosis extended into the underlying muscle. In the second (doubtful) case the changes were similar but minimal in degree. In two of the cases deposits of lime salts seemed to be visible on x-ray examination; in a third, where lime salts were evident microscopically, they were not shown by x rays. These appearances, occurring in cases of chronic but yet fairly severe and extensive sclerema, are interpreted by the authors as those of chronic inflammation and its sequelae.

The results of the elaborate and carefully controlled chemical examinations were also interesting, and perhaps even more important. They begin with reference to Langer's theory of an abnormal constitution of the fat in sclerema, and to the still earlier theory of the influence of cold; but they go much further, and establish new and important facts in the chemistry of subcutaneous fat, normal and diseased. It has already been established that the melting point of the subcutaneous fat of healthy young infants is

higher than that of adults, and it seems reasonable to ascribe this to the smaller content of olein and the relatively greater content of palmitin and stearin, which is also an accepted fact. This normally high melting point in the fat of healthy infants is still further, but not greatly, raised in sclerema fat. The question therefore arises whether this greater solidity of the fat in sclerema is due to a further reduction in the olein content. Some observers have answered this in the affirmative, others in the negative. Dr. Harrison found no significant reduction of olein in his cases, but nevertheless thinks it possible that a slightly higher proportion of palmitin and stearin might account for the raised melting point of sclerema fat; though the cholesterol content was also increased, he is satisfied that this was not a factor in the raised melting point. With regard to the abundant acicular crystals that were such a prominent feature in the sections, important and definite conclusions were reached. These also are apparent in normal fat cells, and in both cases give similar chemical reactions and are anisotropic to polarized light; they are probably neutral fats of the higher series, and it is unlikely that they are cholesterol compounds; in sclerema they probably exist in crystalline form during life. An excess of calcium and phosphorus was also found in sclerema fat.

The broad result of this careful and controlled analysis is that the chemical constitution of sclerema fat is not greatly different from that of the normal subcutaneous fat of young infants, and that the histological picture indicates a definite process of chronic inflammation. After a very judicious weighing of the evidence Dr. Harrison's provisional conclusions are rather against a primary disorder of chemical constitution and metabolism; he thinks it is probable that the inflammatory changes are primary and determine the abnormal chemical condition of the fat. No evidence of bacterial agency was obtained; but it is hoped that further cases will give opportunity of investigation along these lines. This brief account will serve to show what a valuable contribution to the problem of sclerema neonatorum has been made. By this laborious spade-work some obstinate and disputed questions have been answered, and one or two paths have been cleared which promise further progress towards the final elucidation of the disease.

## THE EPILEPSIES.

The lecture by Dr. Kinnier Wilson published in this week's JOURNAL (p. 1) includes a helpful critical survey of some of the numerous theories which have been formulated to account for the various clinical symptoms to which the term "epileptic" is applied. The views he expresses must carry no little weight, since they are based upon a wide experience of epilepsy in all its manifestations, and also upon a number of clinical researches in the sphere of neurology which have a direct bearing upon the physiology and pathology of convulsive episodes.

There is no disease which merits more attention than epilepsy. The number of cases is not small, and the symptoms included under this heading are of such a kind as to be disastrous to their subjects, and even when manifested in mild form, seriously diminish their social efficiency and opportunities in life. In spite of the vast amount of investigation which has been directed to epilepsy and other apparently related forms of nervous disease, we know but little of their causation, and treatment can thus only be palliative rather than curative. Dr. Wilson fully recognizes this

<sup>1</sup> An Investigation of Sclerema Neonatorum, with Special Reference to the Chemistry of the Subcutaneous Tissues. By G. A. Harrison, B.A., M.D.; with a Histological Report by J. W. McNee, M.D., F.R.C.P. *Archives of Disease in Childhood*, April and June, 1926. London: British Medical Association House, Tavistock Square, W.C.1. Yearly subscription (6 numbers), 25s.; single number, 4s. 6d.

fact; he points out that the physician must know the nature and etiology of the morbid condition with which he is dealing, and the mechanism of production of its symptoms, before he can obtain that definiteness of treatment which must always be his goal. He observes, furthermore, that while the external manifestations of an ordinary epileptic fit are apparent to everyone, its inward or neural genesis and progression offer problems of great difficulty and complexity, on which the outward phenomena at the best throw but an imperfect light. Like some other nervous affections, he adds, epilepsy is a condition easy of diagnosis but etiologically and pathogenically obscure, and wide excursions in neuro-physiology and experimental neuro-pathology have to be taken to gather such relatively meagre data as are at our disposal in this connexion. It is because Dr. Wilson has himself undertaken these wide excursions that we feel he is in a position to contribute something of value to our knowledge of epilepsy. A few comments may be made on his views as to the organic nature of epilepsy, as this aspect of the problem is one of considerable importance in view of the contradictory theories which have been formulated regarding the genesis of epileptic symptoms.

During the last few years much attention has been devoted to the psychogenetic factors entering into the causation of nervous and mental symptoms, and to the possibilities of their cure or amelioration by psychotherapy. The value of these conceptions and modes of treatment must not be underestimated, and it is now generally recognized that formal or informal psychotherapy bulks largely in the treatment of disease, both functional and organic. Even in the treatment of epilepsy the personality has to be considered as well as the disease, and the importance of psychological methods of approach cannot be eliminated. Thus such questions have to be considered as the attitude of the patient to his disease, the avoidance of emotional stress, the provision of suitable occupation, and the elucidation of conflicts. It is quite another matter, however, to ascribe the symptoms in the epilepsies to psychogenetic causes, as has recently been done by some clinicians, especially by those of the psycho-analytic school. According to the theories which have been formulated by these investigators, the epileptic episodes are to be regarded as the outward expression of an inward need, craving, or impulse. A state of inner tension is assumed to be created by an unconscious wish, and the fit is its method of release—a dramatic gesture, as it were, on the part of the unconscious which restores psychic equilibrium. Such theories are not unattractive, though the various speculations to which Dr. Wilson refers in his lecture as to the "meaning" of the fit are not of a kind to carry conviction. In the severe psychoses we know that patients assume postures, and exhibit resistiveness, rigidity, and prolonged states of stupor which are clearly the external expression of ideas or cravings which control the personality. It is most difficult to believe, however, that an epileptic fit is a similar form of "behaviour"—the assumption of a posture or an attitude to life. Dr. Wilson strongly deprecates such a view, and is convinced of the physical or organic nature of epileptic phenomena. Personal observation and study of many hundreds of epileptic fits, both general and Jacksonian-becoming-generalized, have not satisfied him either that all epileptic fits, roughly speaking, are alike, or that any definite scheme or organization of movement is revealed in their manifestations. On the contrary, he follows Hughlings Jackson in holding that a con-

vulsion is a "contention of complex, and also of simplest, movements. In this contention the individuality of each movement is lost." The tonic stage he also regards as a "single big useless movement," followed at length by a succession of such rigid states, a clonic stage, a series of so-called movements "which do nothing but 'mark time.'" Holding these views of the physiological phenomena of a general convulsion, Dr. Wilson is unable to accept the psychological theories of their origin. He does not consider that the movements in a fit have any "meaning" whatever, or that they are of more significance than an explosion of gunpowder. He adds that even in respect of the "march" of movement in a Jacksonian fit, the clinical type of exaggerated, caricatured movement in no way resembles those that are called "voluntary" or purposive, while the "march" of the movements follows anatomico-physiological lines alone, and presents no point of comparison, but many of contrast, with the co-ordinated movements of a limb in health.

Though we recognize the value of studies of the personality in epileptics, the arguments in favour of an organic or physical rather than of a psychological basis of the symptoms in epilepsy would appear to be overwhelming. It seems, therefore, unlikely that the prospects of curing epilepsy by psycho-therapeutic methods, however elaborate and prolonged, are very hopeful. It would also seem probable that investigations along neuro-biological rather than along psychological lines are more likely to lead to a better understanding of this distressing malady, and thus to a more effective curative rather than palliative treatment.

#### THE PRACTICE OF PREVENTIVE MEDICINE.

NEARLY seven years ago, when the Ministry of Health was still in its infancy, there was issued *An Outline of the Practice of Preventive Medicine*, written by Sir George Newman, who was then, as now, Chief Medical Officer of the Ministry. It was called a memorandum, but had many of the features of a good textbook. It was addressed primarily to local authorities and their officers, but also to voluntary workers of all classes and kinds devoting themselves with public spirit to manifold services on behalf of the health of the nation. In commenting upon the first edition we observed that in the section on the prevention and treatment of non-infectious disease opinions and statements were encountered which were novel in an official report. It was perhaps partly on this account that the book made a strong appeal to the medical profession, and that it had a very considerable circulation among its members. It was, we said, to be expected that the author would instance the prevention of heart disease, of rickets, and of dental caries, and we welcomed a short essay on preventive surgery, defined as consisting of two parts—reconstruction by anatomical restoration and re-education of function. In the interval much light has been thrown on the prevention of rickets and on the prevention and importance of dental caries, and the information obtained has been practically applied. So, also, orthopaedic surgery has made great strides, and gradually the whole country has been covered with a network of dispensaries and hospitals. In the matter of the prevention of heart disease we have not got very far, but the subject has been more fully discussed than ever before, and facts and opinions have been brought to a focus in the report of the sub-committee appointed by the British Medical Association, which is published in the Special Supplement to this issue. As we have observed elsewhere, it will, we trust, mark a transition from discussion to action. Incidentally, it may

induce Sir George Newman in any future edition of his essay to transfer rheumatism and the heart disease it produces from the class of non-infectious to that of infectious diseases. The original edition of the essay has been for some time out of print, but the demand for it, both in this country and abroad, continues, and it has therefore been thought advisable to issue a new edition.<sup>1</sup> The form remains unchanged, but the opportunity has been taken to add a considerable amount of new matter to the text, and to revise the whole. The sections on rickets, on mental disease, and on dental disease have, for instance, been expanded, as has also that on industrial hygiene; that on alimentary disease seems to have been largely rewritten. Since the first edition was published in 1919 the General Medical Council has revised the medical curriculum, and one of the main objects of the changes made was to ensure that all forms of clinical medicine should be permeated with the idea of prevention; for example, provision is now made for instruction in ante-natal conditions and infant hygiene, and each student is required to undertake the duties of an intern in a lying-in hospital. These facts are duly noted, and all the way through the needs of the student are borne in mind. The essay, therefore, which we are glad to note has been issued at the low price of 1s., may well be bought by students as one of their textbooks; some of them, and these among the best, often get bewildered as to the meaning of the curriculum—they cannot see the wood for the trees. Sir George Newman has a good deal to say which will help them—and help, too, very many men in practice, especially the younger men, who also are inclined to cry, "What is the good of it all?"

#### RESEARCH DEFENCE SOCIETY.

THE annual meeting of the Research Defence Society was held on June 25th under the presidency of Lord Lamington. Both he and Lord Knutsford paid sympathetic tributes to the work of the late Mr. Stephen Paget, the founder of the society. Lord Knutsford said that he did not think he had ever known a truer friend or a more lovable soul. Stephen Paget had been held up by those who opposed him as a man who loved controversy for its own sake. That was not so. No man liked controversy less, but he hated anything that savoured of untruth or misrepresentation, and made war upon it unhesitatingly. His death was a great loss to the society, whose existence he had safeguarded through some difficult times; it was proposed to establish a Stephen Paget lectureship as a memorial. Sir David Ferrier, in presenting the accounts of the society, said that the financial position had much improved during the year, owing principally to a legacy of £1,000 under the will of Dr. John Hall. After the formal business had been disposed of, Dr. J. A. Murray, F.R.S., director of the Imperial Cancer Research Fund, gave an address in which he said that experimental study of cancer started some twenty-five years ago, and its course might be divided into three periods. The first began with the work of Jensen and Borrel on transplantation, and the second was marked by the work of Fibiger and Yamagiwa and their followers, in which the production of cancer *de novo* in normal animals was achieved. The third period overlapped the second, and embraced the work of Peyton Rous, Blumenthal, Gye and Barnard, and others, on the possibility of micro-organisms entering into the mechanism of cancer origins. In general it might be said that the experimental investigations had made the definition of cancerous processes more precise, and had enabled a decision to be made between alternative statements of problems either of which

might otherwise have been taken to be true. Jensen and Borrel at the end of last century showed that cancerous growths could be propagated in series in normal animals of the same kind by the introduction of fragments of original growth under the skin. The constant repetition of the same features in a succession of experiments on transplanted cancer in mice permitted the conclusion that the cancer cell behaved as it did because of differences inherent in it, or permanently imposed upon it, and not because of the peculiarities of the individual in which the growth had arisen. Jensen also observed that an animal which had resisted a first transplantation was more immune to a second transplantation, though when workers began to use this process of immunity for transplanted tumours they found that even very energetic methods of immunization did not avail to stop the growth once it had started. The second-period of cancer research concerned itself with the production of cancer *de novo*, not merely with its continuation and transplantation. Cancer might arise from exposure to products of shale or coal distillation, or to physical agents such as heat, ultra-violet rays, and x rays. He described in particular the work on growths produced by tar in mice, and pointed out that the cancerous proliferation did not begin all over the area to which the tar was applied. Cancer was not a direct response to the irritant action of tar. After the process had started the growth still went on though the application of the tar was stopped. The tar evidently set up a condition which made the cancerous change possible. If a tar cancer was produced in an animal, and then removed by operation, a second tar cancer was more difficult to produce; it was true also that a second cancer was more difficult to produce if the first had been a spontaneous cancer which had cleared up. In discussing the third stage of progress Dr. Murray came to the work of Gye and his colleagues. It was still too soon, he said, to express a final opinion on the validity of Gye's views, but it was only fair to say that this was the first time that the microbic formation of cancer had been presented in a form not incompatible with the known facts of cancer structure and behaviour. Dr. Murray said, in conclusion, that it had often been stated, and was likely to be stated again, that the key to the secret of cancer would probably be found in some other direction—in electrophysics, for example, or in chemistry, or embryology, or what not. This suggestion was always presented in a vague form and in rather high-sounding phraseology. He suspected that it arose from a very human weakness which supposed that the cancer problem could be elucidated by going round to the back door. For his own part he did not believe it. Experiment had defined the problems, and it was only by first-hand acquaintance with the facts that a just statement of the position could be kept before the mind of the investigator.

#### SUBURBS OR SATELLITE TOWNS.

WRITING in *Barnaby Rudge* of the year 1775, Charles Dickens says of Clerkenwell that although this part of the town was parcelled out in streets and plentifully peopled, "there were gardens to many of the houses and trees by the pavement side, with an air of freshness breathing up and down which in these days would be sought in vain. Fields were nigh at hand. . . . Nature was not so far removed or hard to get at as in these days." The extent of urbanization of London since the days of Dickens has forced itself on the notice of the public, and the London County Council appears to be willing to take steps to preserve the amenities, beauty, and convenience of two sites in Bloomsbury (one comprising the Foundling Hospital), and to retain their residential character. In both these areas are squares which almost daily must have delighted the eyes of the great novelist. The area of these

<sup>1</sup> *An Outline of the Practice of Preventive Medicine. A Memorandum addressed to the Ministry of Health by Sir George Newman, K.C.B., M.D., F.R.C.P., Chief Medical Officer to the Ministry. Second revised edition. 1926. H.M. Stationery Office, or through any bookseller. Price 1s. net.*

sites, however, is small in comparison with the size of London and of Greater London, which is always extending its growing edge. London requires an increase of 2,000 acres a year to house the normal increase of its population. But the ugly suburbs of the past need not be reproduced; not only must new dwellings be judiciously and hygienically distributed, but the beauty of the country must be saved as far as possible. The preservation of open spaces in advance of development is an urgent problem which, although possibly worse in London, is acute also in other large towns. If land is not ear-marked shortly for the purposes of open spaces the development induced by town planning will increase the price that must be paid for it. There seem to be two alternatives—namely, suburbanization, which, as we pointed out some months ago, must be effectively controlled if the mistakes of the past are not to be repeated, and satellite towns. If prompt action be taken a more or less complete ring of park land for purposes of recreation could probably be provided within nine miles of Charing Cross. Many hold that London is already many times too big, and that the problem of the future extension of the metropolis could best be solved by the creation of satellite towns on the lines of the Letchworth and Welwyn garden cities. By the extension of suburbs which has already occurred, London workers now have to go further and further out, and a longer and longer journey twice a day is necessitated. The expense, the waste of time which might otherwise be spent in healthy exercise, the fatigue induced by travelling in oscillating and noisy trains, the effects of vibration on the central nervous system, the respiratory diseases contracted during inclement weather by waiting on draughty platforms, the spread of communicable diseases by overcrowding in railway carriages—these are some of the drawbacks of the present system. The difficulty created by the fact that workers, including clerical workers in what may loosely be called Central London, need to live far out was very noticeable during the general strike. In a satellite town life might be more like that of the old provincial town, with its larger measure of peace and repose and home life, absence of hurry, the walk to and from work, the midday meal at home, and the quiet, calm performance of the daily task. The satellite town contains not only homes for workers, but factories for them to work in, and commerce and business to engage other members of the family. Fortunately, the problems are being considered; legislation has been promised concerning areas already built on, and in reply to a recent deputation on the need for a comprehensive scheme for the development of London and the Home Counties the Minister of Health expressed the opinion that a plan prepared by impartial experts, and not by a body composed of interested parties, might be generally acceptable; he also promised to convene a conference, if the willing consent of the local authorities could be obtained.

#### THE RENAISSANCE OF MEDICINE IN CZECHO-SLOVAKIA.

THE revival of the study of medicine in Czecho-Slovakia since the war is the theme of a special medical supplement of the *Central European Observer*, a weekly journal published in Prague. Dr. Charles G. Reinhorn of Montreal, operator in the first surgical clinic of the Charles University of Prague, gives a summary of the history of the country, which has been known successively as the Moravian empire, the kingdom of Bohemia, and now Czecho-Slovakia. He points out also that near Carlsbad is one of the principal sources of radium; that mineral waters are found at Karlsbad, Marienbad, Franzensbad, Joachimsthal, Pistany, and elsewhere; that a new hygiene institute has been established; and that the gymnastic society, Sokol, is the greatest in the world. Professor Ladislav Syllaba, president of the Czech Medical Society,

writes a historical sketch of the medical profession in Czecho-Slovakia. He shows how the attempts at development in medical science were handicapped by the obstruction of the Government at Vienna, and describes the efforts of the famous physiologist, whose name, it appears, should be written Purkyně, after a measure of freedom had been obtained for the country about 1860. Owing to the opposition of Austria it was impossible to establish a second Czech university until after the war. Now there is a third, as well as numerous medical societies; and many medical textbooks and periodicals have appeared. These developments have been assisted by the Rockefeller Foundation, through which also the new Hygiene Institute was made possible. According to Professor Syllaba, the Czechs desire to have a national science of their own to enable their intellectual life to develop all round, and at the same time they wish to be closely connected with world ideas. One of their difficulties in realizing this ideal is to be found in their language. Further articles in the special supplement deal with the history of Czech surgery, the Czech clinic of obstetrics and gynaecology, the educational work of the Jedlicka institute for cripples, the clinic for oto-rhino-pharyngology, the institute of plant physiology, and the Czecho-Slovakian spas and health resorts. The visit of a party of English medical men to some of these spas, in connexion with the annual meeting of the International Society of Medical Hydrology, was described in the *BRITISH MEDICAL JOURNAL* of June 19th, 1926 (p. 1045). The special medical number of the *Central European Observer* is illustrated with photographs of Prague and its institutes and clinics. It was published on the occasion of the visit of the members of the Inter-State Post-Graduate Assembly of America to Prague in June.

#### THE CENTENARY OF LAËNNEC.

THE centenary of the death of Laënnec is to be celebrated in France, both in Brittany, where he was born and died, and in Paris, where he lived and worked. Laënnec, who came of a family most of whom practised some profession, and many of them the law, was the son of a barrister, and was born at Quimper on February 17th, 1781. While still working in Paris he acquired and partly rebuilt the manor of Kerlouarnec, at Ploaré, near Douarnenez, which is not very far from Quimper, and to this secluded spot he had retired in June, 1826. His death, which, as is well known, was due to phthisis, occurred on August 13th in that year. The celebration in Brittany is to take place on August 12th. There will be a service in the parish church, and the Bishop of Quimper will preach a sermon; afterwards a procession will be formed to visit the cemetery, where speeches will be made—the first by Dr. Mével of Douarnenez, the second, in the Breton language, by M. Poulhazau (advocate), and the third by Professor Chauffard (the president of the centenary committee formed in Paris). Then there will be a banquet; after that a visit will be paid to the manor of Kerlouarnec, where the present owner, who is the mayor and a councillor-general, will make a speech. We should imagine that a visit to this part of Brittany, which is close to the sea—in fact, the manor house looks out on the sea—might be very pleasant if the weather is kindly. Apparently English visitors will be welcomed, and can find hotel accommodation either at Douarnenez or at Quimper. Rooms ought to be secured before August 1st. Those who wish to go to the banquet must send a subscription of 20 francs ten days in advance to M. le maire de Ploaré, par Douarnenez (Finistère). The celebration in Paris will take place in December (13th, 14th, and 15th); it is being organized by the Academy of Medicine, which has appointed a committee with Professor Chauffard as president. We are informed that this celebration, which will commemorate both Laënnec's death and the publication of

the second edition of his famous work the *Traité d'Auscultation*, will be attended by many foreign delegates. The treasurer of the Paris celebration is M. P. Masson, 120, boulevard Saint-Germain, to whom subscriptions should be sent.

#### THE VENTILATION OF HUMID WEAVING SHEDS.

WORKERS engaged in cotton weaving have frequently raised strong objections to the artificial humidification of the air in the weaving sheds because of the personal discomfort it entails. Unfortunately it is difficult to abolish it, as it greatly increases the efficiency of the weaving process owing to its influence on the breakages of the warp threads. In Report No. 37 of the Industrial Fatigue Research Board Mr. S. Wyatt, who was assisted in his investigation by Mr. J. A. Fraser and Mr. F. G. L. Stock, has shown that the discomfort due to humidification can be very greatly diminished by installing electric fans in the sheds. Such fans were found to increase the air movement so much that the cooling power of the air, as estimated by the dry katab-thermometer, was raised from 4.2 to 5.6. Expressed in other words, the cooling power of the air was greater at a temperature of 80° F. when the fans were running than at 72.5° when they were stopped. The increased air movement produced by the fans had no significant effect on the number of warp breakages, and, indeed, the output of the weavers was distinctly increased on the days when the fans were running. This effect was specially noticeable on days when the temperature or the humidity was unusually high, the output being increased some 10 to 20 per cent. towards the end of the work spells. A statistical analysis of the results obtained at different temperatures and humidities showed that the highest output from the looms was obtained at a temperature of about 74° and a relative humidity of 77 per cent. Though higher temperatures and humidities reduced the number of warp breakages, yet their adverse influence on the workers themselves was more than sufficient to discount the better physical conditions for weaving. Though the installation of electric fans is rather expensive, it is probable that a number of small fans operated mechanically by the looms could be substituted. The cost of running such fans would be almost negligible, and they would have the additional advantage that they could be switched on and off at the discretion of the individual weaver.

#### THE EMPLOYMENT OF SUGGESTION IN SURGERY.

WE have frequently had occasion to mention the publications by Victor Pauchet, surgeon to St. Michael's Hospital, Paris, dealing with practical surgery, and we have recently reviewed his work *Practical Surgery Illustrated*, first in the original French and later in its English translation. An article by him on the use of psychotherapy in surgery has been published in the May issue of *Minnesota Medicine*; in it he recommends the combination of suggestion with certain physical methods, and describes the treatment of a case of extreme gastroparesis in which an operation was inadvisable owing to debility, emaciation, and acidosis. The patient was given a spirometer and was encouraged to record the increasing lung capacity, with the consequent improvement in appetite and general condition. The amount of air exhaled rose from 200 c.cm. to 2 litres in a fortnight, and to 3 litres later; recovery was completed without surgical treatment. Pauchet recommends the use of the spirometer on these lines for such other conditions as salpingitis which necessitate confinement to bed, resulting in muscular atrophy, the accumulation of fat, and diminished will power. He finds suggestion valuable also in pre-operative and post-operative treatment, and emphasizes the importance of removal from the patient's environment of any relative or nurse whose

influence is depressing. Friction and massage should be supplemented by voluntary deep breathing. Pauchet lays stress on the effect of long-standing disease upon the patient's mind and spirits. Continued pain, chronic toxic absorption, prolonged debility, and repeated surgical operations result in changes in the metabolism, endocrine insufficiency, and deterioration of the character and will power. Such patients require mental re-education and respiratory exercises, in addition to the more specialized treatment. Such physiotherapy and psychotherapy, Pauchet adds, will aid the beneficial action of surgical and medical measures if the practitioner recognizes that the action is a personal one, and that the healer, rather than the method of healing, is the essential factor.

#### PAY OF R.A.M.C. OFFICERS.

MUCH satisfaction will be felt by the publication this week of the Army Order regarding the rates of pay and retiring gratuities of the medical services, the details of which we give in another column. Our satisfaction is all the greater because the British Medical Association was in a considerable measure instrumental in bringing about the change of attitude towards the medical services which His Majesty's Government has now displayed. But we ought also to recognize the influence of the late Director-General, Sir William Leishman, in the fact that effect has now been given to proposals with which, we believe, he was always in entire sympathy. The increases in the rates of pay and retiring gratuities are substantial, as will be readily seen in comparing the new rates with the old rates promulgated by Royal Warrant after the war. But both the old rates and the new rates, as will be observed, are subject to the 5½ per cent. reduction owing to the decrease in the cost of living. The increases in pay do not begin until after six years' commissioned service, but from that time onwards, especially in the rank of major, very much has been done to make the service more attractive. One of the chief grievances, it will be remembered, was the fact that a major, after three years in that rank, or fifteen years' commissioned service, got no increase of pay until he was promoted to the rank of lieutenant-colonel, a promotion which might possibly not take place until he had as much as twenty-four years of service. The new Warrant gives him a steady increase of pay, not only after fifteen years' service, but also after eighteen or twenty years' service. The ranks senior to that of major also participate in very substantial concessions, and this although their case was not so hard as that of the majors. The Director-General's position, however, was not so good as that of other officers of his rank. This has been remedied, and instead of receiving a consolidated pay of £2,500 a year, he is now placed on exactly the same footing as other lieutenant-generals, being granted the pay and allowances of that rank. The retiring gratuities of a major after three and six years' service are now perhaps so great as to induce officers to retire before they become eligible for a pension, but in that case it is hoped that they will only make room for a large influx of junior officers to carry on the duties that are now being performed by those more senior in the service. The British Medical Association held out strongly for the removal of a serious grievance in regard to the retiring pension of an officer after twenty years' service, and it pointed out that it was possible in the future for a major to have to retire on a less pension than £1 a day, which had been granted to him from time immemorial. The new Warrant relieves him of anxiety in this respect, and explicitly states that his pension cannot be reduced below that amount. Although we are not prepared at present to comment further upon the effect of these changes in the Army Medical Services, as there may be one or two points that are still worthy of consideration,

more especially as regards limiting the period during which a lieutenant-colonel remains in that rank before going on half-pay or retired pay, we hope that the concessions now made will bring about a marked change in the number of candidates applying for commissions in the Royal Army Medical Corps. We have still to see how far the Indian Government will accept the new rates for R.A.M.C. officers serving in India. One important point should be noted—namely, the concession by which a newly qualified medical man can hold a hospital appointment for one year before entering the service, counting it as a year of service towards promotion and retirement. Previously this concession was only given after the officer had entered the service. This was one of the points that was strongly brought forward in the evidence submitted by the Association to the inter-departmental committee, and should give special satisfaction to members of the medical profession. As we have been more concerned recently with the grievances of the R.A.M.C. than with those of the other services, we refrain from commenting at present on the concessions granted to the Royal Navy and Royal Air Force Medical Services; but it will be seen that both of these services have also benefited considerably by the recommendations of the committee.

#### MEDICAL CHARITIES AND INCOME TAX.

THE decision of Mr. Justice Rowlatt in the case of two medical charities deserves more attention than considerations of time and space permitted us to pay to it last week (p. 1107). The societies concerned were the Society for the Relief of Widows and Orphans of Medical Men and the Medical Charitable Society for the West Riding of Yorkshire, and the circumstances of the two cases were sufficiently similar to enable them to be argued and decided together. That the matter was one of real importance is indicated by the fact that in the former case alone a sum of about £800 a year was involved. The contention of the societies was that they had become possessed of funds by way of legacy, donation, and subscription which they held for clearly defined purposes—briefly, for the relief of indigent members or their dependants—and that the income derived from their investments had to be, and was in fact, so applied, that those purposes had been recognized by the Court of Chancery as “charitable,” and therefore that the societies were entitled to the exemption provided in the income tax Acts for income held on trust and applied for charitable purposes only. Counsel for the Crown relied in the main on the argument that in substance the societies were carrying on provident and benevolent institutions rather than acting as trustees of a charity, the suggestion being that as the grants made to members or their dependants were met in part from subscriptions of themselves and other members, it was to that extent a semi-contractual arrangement for mutual assistance among a definite group of persons, and that consequently the funds were not held on trust “for charitable purposes only.” Mr. Justice Rowlatt did not accept that view. As he pointed out, it was true that doctors were invited to qualify for contingent relief by these societies, but the funds were in the hands of trustees who, of course, were bound to discharge the duty of granting relief faithfully. It seemed to him that there was in those societies the element of relief of poverty outside the contractual relief of poverty, and he held that both were charitable. The medical profession, and doubtless other professions too, are to be congratulated on the result of these cases. If income tax were payable on the income of such societies it would grievously cripple the very important and beneficent work they are doing, not merely because it would seriously reduce the income immediately available, but also, it is to be feared, by its effect on future donations and bequests. The modern representative of the old “pious benefactor”

is frequently a shrewd man in his charities as well as in his profession, and it is only to be expected that in selecting the channel by which his benevolence is to seek an outlet he will avoid one which is liable to be tapped to the extent of 20 per cent. for income tax. Such societies do an excellent work in gathering together donations and bequests, as well as subscriptions, into one fund, and then effecting the distribution of the income with care and knowledge; it would have been a matter for keen regret if an adverse decision of the court had impeded their continued and successful activity.

#### OXFORD OPHTHALMOLOGICAL CONGRESS.

THE annual Ophthalmological Congress in Oxford will be held on July 15th, 16th, and 17th. The members will dine together at Keble College on the evening of Wednesday, July 14th, and will start work in the Department of Human Anatomy of the University Museum at 10.15 a.m. on Thursday, when Mr. Philip H. Adams, surgeon to the Oxford Eye Hospital and Master of the Congress, will give a brief opening address; this will be followed by a discussion on sympathetic ophthalmia, introduced by Mr. Malcolm Hepburn, surgeon to the Royal London Ophthalmic Hospital, and Mr. S. H. Browning, bacteriologist to the same hospital. Mr. Hepburn, considering the fear of the older generation of surgeons that sympathetic inflammation may develop many years after an accident, and believing that that is not now the general opinion of ophthalmologists, will urge the necessity for some scientific method by which cases due to sympathetic inflammation and those due to other causes may be distinguished, and that operation can properly be undertaken for the relief of symptoms in the injured eye. Mr. Browning will deal chiefly with the differential blood count in sympathetic inflammation as a guide to the decision whether an eye should be removed. In this discussion Professor Emile De Grosz (Budapest) will take part. The afternoon will be filled chiefly by attending a number of demonstrations, and the annual dinner will take place in Keble College in the evening. On Friday morning addresses will be given by Dr. George Young (Colchester) and Dr. Marion Gilchrist (Glasgow), and Mr. Thomson Henderson, surgeon to the Nottingham Eye Infirmary, will deliver the Doyne Lecture on the anatomy and physiology of accommodation in mammals. At the Oxford Eye Hospital in the afternoon Lieut.-Colonel Henry Smith, C.I.E., I.M.S., will open a discussion on intracapsular extraction of cataract. On the morning of Saturday, July 17th, Dr. T. S. Good, medical superintendent of the Oxford City and County Mental Hospital, will give an address on psychology and the eye, Dr. T. Harrison Butler will speak on inflammation of the eye as seen by the slit-lamp, and Dr. Margaret Dobson on ophthalmoscopy of the macular region by red-free light. During the congress an exhibition of ophthalmological instruments and apparatus will be held in the Department of Human Anatomy. The subscription to the congress is one guinea, which should be sent to the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton, who will supply fuller particulars about the congress.

We regret to announce the death, after a brief illness, of Mr. W. H. Clayton-Greene, who retired a year or two ago from the post of surgeon and lecturer on surgery at St. Mary's Hospital, and went to live in Guernsey.

THE Home Secretary has appointed Sir Hugh Anderson, M.D., F.R.S., Master of Gonville and Caius College, Cambridge, to be a member of the Advisory Committee on the Administration of the Cruelty to Animals Act, 1867, in the place of Sir John Rose Bradford, M.D., F.R.S., who resigned from the committee upon his election as President of the Royal College of Physicians of London.

## MEDICAL WORK IN KENYA COLONY.

REPORT FOR 1924.

As is made plain in the recently issued report for the year 1924,<sup>1</sup> the activities of the Medical Department and Medical Research Laboratory in Kenya Colony have been sadly hampered for lack of funds in these hard times. Out of a total expenditure bordering on £2,000,000, the Kenya Legislative Council allotted some £127,000 to the Medical Department for the year, not all of which, for various reasons, was expended; rather more than £12,000 was collected as revenue by the department.

The report gives a full and statistical account of the work done by the whole Medical Department, and contains a quantity of information that should be of great interest to the medical men working in a number of our colonies.

The treatment of jaws and syphilis, two diseases it is generally impossible to distinguish, with intramuscular injections of sodium potassium bismutho-tartrate continued to give good results in the native population, and was highly appreciated by its recipients; over 56,000 cases were treated. Plague, which is endemic in Kenya Colony, was less in evidence than it was in 1923. The report states that in the Central and North Kavirondo districts, where the incidence of plague was greatest, a campaign against rats has been carried out since July, 1921; some five million had been destroyed down to the end of 1923, and over 1,300,000 in 1924. It is unfortunate that it has been found impossible to draw any general conclusions as to the effect of this destruction of rats on the incidence of plague in these districts; there was less plague in them during 1924, but the same was the case in the rest of the colony generally. Malaria is always the cause of a great deal of acute and chronic sickness in Kenya Colony, and 19,000 cases of it were treated in the Government hospitals and dispensaries, with 40 deaths; examination of blood smears in the laboratory showed 308 cases of subtertian, 47 of benign tertian, and 19 of quartan malaria. An interesting series of cases of subtertian malaria, in which the temperature remained normal or subnormal, was observed in the native hospital at Nairobi; it is said that clinically there was little to suggest malaria.

Of undulant (or Malta) fever there were 14 cases; it appears that the bacillus of contagious abortion in animals (*B. abortus* Bang) is capable of infecting human beings with undulant fever, and the report adds that the relationship between the *Micrococcus melitensis* and the *Bacillus abortus* in Kenya requires investigation. For the first time in the history of the colony diphtheria was encountered in 1924, there being 11 cases (6 in Europeans, 2 in Asiatics, and 3 in Africans), with no deaths; the cases were sporadic.

Full details of the provisions made for the health of contract labourers in the colony and of the labour employed on railway construction are given, with figures showing the good effect of these provisions in the case of the latter. The report contains full accounts of the sanitation work, the work in maternity and child welfare, school inspection, the work of the Government hospitals, dispensaries, and institutions generally, that cannot be further noticed here, together with many pages of statistical returns.

The annual report of the Medical Research Laboratory at Nairobi shows that the time of its staff was mainly occupied with routine clinical examinations during 1924; in addition 124,000 doses of plague vaccine, 225,000 doses of sodium potassium bismutho-tartrate for the treatment of jaws, and 123,000 doses of calf lymph were turned out. Specimens from no fewer than 17 cases of malignant disease in natives were received, as compared with 5 in 1923, 5 in 1922, and 2 in the eight previous years. This increase coincides with the opening of new dispensaries and hospitals in the native reserves, and seems to show that malignant disease is not unknown (as is so often stated) among primitive and uncivilized races. Examination of over 250 samples of the milk from native humped cows showed an average of 14 per cent. of solids, of which 4.6 per cent. was fat; the average specific gravity was 1.033. It is of interest to note that up to 88 per cent. of

water was found in specimens of *Podocarpus* timber, a wood much used locally in carpentry and joinery work and distressingly given to warping when set up. Finally it may be mentioned that salts of zinc were found constantly in the water of the Nairobi water supply, and that experiments made by the analytical chemist seemed to show that the zinc came from the lining of the "galvanized" water piping employed, being dissolved by the carbon dioxide contained in the water. Removal of the carbon dioxide by adding a proportion of lime to the water prevented this solution of the zinc lining of the pipes. The occurrence of pipes (from kitchen boilers) blocked with a deposit of zinc carbonate is recorded.

The report, printed by a local firm, is well turned out; and its contents show that, in spite of the obstacles imposed by a restricted finance and the many discouragements met with by scientific workers in newly developed lands, the Kenya Medical Department did admirable work during the period under review.

## England and Wales.

## JUBILEE CONGRESS OF THE ROYAL SANITARY INSTITUTE.

The Royal Sanitary Institute, as already announced in these columns, is celebrating its jubilee by holding an imperial congress in London from July 5th to 10th. The congress is meeting under the presidency of the Minister of Health (the Right Hon. Neville Chamberlain), who will deliver an inaugural address at the Guildhall on the opening day. About one thousand delegates are expected to assemble, representing Government departments, municipal authorities, learned societies, and the universities; many are also coming from the British dominions and foreign countries. The congress is to meet in six sections and seven conferences. One of the sections, that on sanitary science and preventive medicine, is to be presided over by Sir George Newman; another, on school hygiene, by Lord Eustace Percy, President of the Board of Education. The other sections are concerned with engineering and architecture, personal and domestic hygiene, the hygiene of food, and the hygiene of industry. The conferences include one of representatives of sanitary authorities, under the presidency of the Lord Mayor of London, and one of medical officers of health, with Dr. G. F. Buchan, the medical officer of health for Willesden, in the chair. One session of the congress is to take place jointly with the Maternity and Child Welfare Conference, which is being held in London during the same week. The subject for discussion at this joint conference will be midwifery in the homes of the people, and the medical speakers announced are Dr. E. Kaye Le Fleming, representing the British Medical Association, Dr. T. Watts Eden, and Dr. W. Allen Daley, medical officer of health for Hull. The other discussions of the congress—about sixty subjects are set down—cover a very wide range, from concrete houses to the advantages of cremation, and from the trade pasteurization of milk to health administration in relation to Poor Law reform and national health insurance. Several of the discussions will deal with aspects of medicine, and one, which might be very interesting, is on preventive medicine and the press. The discussions are arranged for the mornings, and in the afternoons there are to be visits to various places of sanitary interest in and around London. Several social functions are also planned, and among those who are giving evening receptions or garden parties are the Duke of Northumberland (president of the Royal Sanitary Institute), the Marquess of Salisbury, and the Lord Mayor and Corporation of London.

## BRITISH HOSPITALS ASSOCIATION AT PORTSMOUTH.

At the annual meeting of the British Hospitals Association, which opened at Portsmouth on June 24th, a welcome was given to the delegates by the Mayor, who referred to the strong support by the city of Portsmouth of the voluntary hospital system. Mr. H. L. Eason, medical superintendent of Guy's Hospital, opened a discussion on the suggested pensions scheme for hospital officers and

<sup>1</sup> The Annual Medical Report of the Colony and Protectorate of Kenya for 1924. Nairobi: Swift Press, Ltd. 1926. (Pp. 113, with tables.)

nurses. Referring to the controversy which had been started by the publication of the scheme, he said that it did not seem just for a voluntary hospital, while appealing for funds as a charity, to carry on its work at the expense of its paid servants, particularly since the King's Fund in its revised uniform system of accounts had recognized pensions as a legitimate part of the annual expenditure of a voluntary hospital; but out of 105 hospitals in London which were in receipt of grants from the King's Fund, not more than six had a general pension scheme. The Whittall Committee had come to the conclusion that hospital officers resembled university teachers as regards migration, and that a federated superannuation scheme on the lines of the parallel scheme for university teachers was the correct solution of the problem. After considering various schemes it had rejected all the mutual schemes and decided in favour of the insurance method. Mr. Eason then discussed the scheme of pensions for hospital officers and nurses suggested by the King's Fund,<sup>1</sup> and commented on certain of its features. He thought it essential that hospital officers should have alternative benefits, since a single man at the end of his career might prefer to have a pension, while a married man with a family might, on the other hand, quite rightly desire to receive a capital sum on his retirement, which he could invest for the benefit of himself and his children, satisfying himself with a smaller income during his life in order that a better provision might be made for his family after his death. Mr. Eason then discussed in some detail the question of contributions towards nurses' pensions and the time at which they should start. In conclusion, he referred to the arduous nature of the nursing career, and added that from October, 1918, to December, 1925, 1,466 nurses had required and received assistance from the national fund; special monetary grants had been made in 1,231 cases, and 30,907 weekly grants had been provided. At the present time 170 nurses were receiving weekly grants, and 130 pensions were urgently required, as the nurses concerned were so incapacitated that they could not be removed from the fund. He believed that a claim for additional support for the purpose of providing pensions for nurses would meet with the readiest response from the charitable public.

#### ORTHOPAEDIC AND SUNSHINE TREATMENT CENTRE IN OLDHAM.

The town of Oldham is to have an orthopaedic and sunshine treatment centre through the generosity of Mr. Richard Greenhalgh of the Vulcan Iron Works. Mr. Greenhalgh has purchased a building in Oldham, and has offered it to the corporation on certain conditions. These are: that the benefit of the institute shall be available to the general public of Oldham, Royton, Chadderton, Lees, and Shaw; that gratuitous patients shall not occupy more than 50 per cent. of the working hours of the institute, the other 50 per cent. being devoted to people who pay a fee to cover the net cost of treatment; that the Health Committee of the corporation shall maintain the institute and pay a rent of £10 a year; and that a provisional lease of three years shall be granted to the Health Committee, at the end of which time the usefulness of the institute shall be reviewed. On these conditions the institute will be fully equipped ready for use. Subject to the conditions stated the offer has been accepted by the corporation of Oldham.

#### PUERPERAL FEVER.

The Minister of Health, it appears, is satisfied, as the result of inquiries, that further special facilities are required in London for nursing and treatment of puerperal fever, with a view to reduction in the mortality from this disease. It has been arranged that in future patients with puerperal fever referred to the Metropolitan Asylums Board shall be concentrated, as far as possible, in the North-Western Fever Hospital at Hampstead, the Eastern Hospital at Homerton, and the South-Western Hospital at Stockwell. Special wards with special medical and nursing staffs will be set aside for these patients. An obstetric consultant has been appointed at these three institutions. The medical

officer of health for Hampstead (Dr. F. E. Scrase) has informed the medical practitioners in his borough that if they will notify cases to him at the earliest possible moment, and if they desire the patient's removal to hospital, he will arrange immediately for the transfer of the patient to the Metropolitan Asylums Board hospital.

#### THE FORBES FRASER HOSPITAL, BATH.

A further step towards the completion of the Forbes Fraser Hospital, Bath, was taken on June 23rd, when Sir Anthony Bowlby, Bt., F.R.C.S., opened the new nurses' home. We described the general plan of the new hospital on July 26th, 1924 (p. 150), and mentioned the further developments contemplated, including the provision of a nurses' home. The mayor, who took the chair at the ceremony, gave an account of the way in which the money for the home had been raised. The memorial fund donations amounted to £2,563, and Mr. Stanley Wills gave £5,000. As the result of a fête held in the spring, £575 had been received, and donations to the amount of £250 had been collected. A sum of £2,200 was, however, still required for some of the furnishing and other expenses. Sir Anthony Bowlby referred appreciatively to the value of the work of the late Mr. Forbes Fraser, who was largely responsible for designing the hospital scheme and for bringing it into fact; the new nurses' home was intended as a special memorial to him.

#### CARE OF THE MENTALLY DEFECTIVE.

The sixty-seventh annual report of the Royal Eastern Counties Institution for the Mentally Defective at Colchester gives an account of the progress made in 1925, and the improvements and extensions proposed to be undertaken with the help of the county councils of Essex, East and West Suffolk, and Cambridgeshire. It is intended to add about 1,000 beds to the existing accommodation, and a building for 444 will shortly be begun. From the report of the medical superintendent, Dr. F. Douglas Turner, it appears that 1,152 patients were under care during the year 1925, with a daily average of 1,066. Dr. Turner discusses the question of sterilization of mental defectives, and comes to the conclusion that it can serve no useful purpose. He agrees with Sir Leslie Scott, president of the Central Association for Mental Welfare, that a general policy of sterilization would be ineffective; that the freedom accompanying it would harm the defectives themselves; that it would delay institutional segregation, which is the only safe procedure; and that it would fail to provide a safeguard either for defectives or for the community.

Mr. Sandeman Allen, M.P., presided at the annual meeting of the West Lancashire Association for Mental Welfare on June 15th. During the year 660 new cases had been dealt with, and 573 patients in the area were under statutory supervision. The association had assisted in designing work for border-line males in Walton Prison, and, with the help of the Liverpool Society of Handloom Weavers, had started a class for spinning and weaving. An appeal was made for the voluntary side of the association's work, which aims at avoiding deterioration and relapse by arranging holidays and other social amenities. Dr. Stallybrass gave an address on the after-effects of crecophyllitis lethargica.

The Agatha Stacey Homes at Birmingham assist the State in the care of the mentally defective. The annual meeting was held on June 9th, under the chairmanship of the Lord Mayor of Birmingham. It was stated that the number of mentally defective persons for whom no institution could be found was appalling; and the suggestion was made that by boarding out some of the persons who had passed the "dangerous age" vacancies could be made for girls who needed direct control.

The annual report presented to the meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded, held at the Manchester Town Hall on June 22nd, stated that during the year the society had added twenty-two acres to its estate, and it was hoped that after certain alterations accommodation for fifty more boys would be provided. There was great pressure for admission of further cases. The accommodation at Sandbridge was fully occupied, the patients numbering 329; some 217 adults had been in the colony from an early age.

<sup>1</sup> BRITISH MEDICAL JOURNAL, 1925, vol. II, p. 1195.

## NURSES' HOME AT THE RETREAT, YORK.

The Retreat, York, was originally established in 1782 by the Society of Friends as a mental hospital, and is an important training school for nurses. A new home for nurses has now been erected at a cost, including fittings, of about £18,000. The building, which is in brick, with a green Westmorland slate roof, stands on an open site, with a rose garden and tennis lawns on the south front, and two hard courts on the west side. It provides accommodation for about sixty nurses and sisters. One wing on the second floor is designed for cases of illness; the ground floor contains separate sitting and dining rooms for the sisters and nurses, and a reading room. Dr. Bedford Pierce, lately medical superintendent, who opened the home a short time ago, referred to the great improvement during the last thirty years in mental nursing. Nowadays each probationer received a technical education, and a great gain in efficiency resulted. The Retreat was almost the first mental hospital to insist that all nurses must take a course of training, and was still the only one which provided that this course should last four years. Owing to the special circumstances of mental nursing the question of general education was even more important than in sick nursing. The nurses should be encouraged to do post-graduate work after registration, and one of the subjects qualifying for a further diploma should be occupational therapy. It was obvious that mental nurses even more than those engaged in general nursing needed reasonable comfort, privacy, and opportunities for study and recreation. Their work demanded perfect fitness of both body and mind, and, therefore, every attempt should be made to give them the best possible environment.

## FIRE PRECAUTIONS IN HOSPITALS.

A memorandum<sup>1</sup> has been prepared by the management committee of King Edward's Hospital Fund for London dealing with fire precautions recommended for hospitals. While the Fund considers that the responsibility for proper provision in case of fire rests with hospital committees, it is thought that notes on the prevention of fire on the lines of those first prepared for the Fund in 1907 would be of service to hospital committees in deciding whether the fire precautions at individual hospitals are adequate. The recommendations relate to the prevention of fire due to oil, gas, electrical appliances, heating pipes, boilers, and open fires, and it is suggested that the obligation of making periodical inspections and reporting possible fire risks should be placed on a competent resident official, who should be specially selected and have charge of the appliances made as to various forms of method of giving the alarm in the memorandum has been drawn up in consultation with Mr. A. R. Dyer, chief officer of the London Fire Brigade.

## Scotland.

## PROBLEMS OF THE BLIND.

At the annual conference of the Scottish National Confederation of Societies for the Blind which was held at Dumfries last month it was reported that an enormous increase had taken place in the number of blind persons under the charge of outdoor societies. In 1920 the number of persons on the rolls of such societies in respect of whom a grant was paid by the Board of Health in Scotland was 3,512; at the end of September, 1925, the number was 5,329, an increase of approximately 52 per cent. The number of teachers had not increased in proportion, for in 1920 there had been twenty whole-time and five part-time teachers, while in 1925 there were twenty-nine whole-time and three part-time teachers. The State and the local authorities under the Act of 1920 have conferred very considerable financial benefits on blind persons and on voluntary agencies for their help, and at the present time the payments made in this way amount to very nearly £100,000 a year. This sum does not include

money paid by Poor Law authorities either for outdoor relief or for technical training, nor does it include the money paid as old age pensions. Dr. Freeland Fergus of Glasgow read a paper dealing with the cause and prevention of blindness. He said that the value of investigations into causes of defective eyesight was chiefly that some forms of eye disease might be found to be preventable. For the last thirty years he had maintained that persons who were going to deal with eye patients should be as thoroughly trained for their work as were medical officers of health. He blamed the General Medical Council for having failed to take any action in this matter. A large number of ophthalmic practitioners were now employed for school work and for panel practice, and all persons so employed ought to have had a special training. He believed that the General Medical Council had been supine in this matter, and he thought, therefore, that the Ministry of Health ought to take the matter in hand; committees to whose care the blind of the community had been entrusted should see to it that this matter was put right. Dr. Fergus referred to the difficulty of treating senile cataract. Out of 121 patients he had found blind from this cause in Glasgow, no fewer than 60 had never been operated upon, and the remaining 61 had been operated upon without success. About 360 senile cataract operations were performed annually in the two Glasgow eye hospitals, and the results in the remaining cases were probably very satisfactory and certainly infinitely better than they were forty or fifty years ago. It was a credit to the public health authorities that only five persons out of 1,200 should have been found blind after small-pox and only one after erysipelas.

The Royal Blind Asylum and School at Edinburgh held its 133rd annual meeting in Edinburgh on June 17th. The Rev. Dr. Burns, chairman of directors, said that the annual report showed that greatly increased interest was being taken in the welfare of the blind, both as regarded the industrial department and the department for technical instruction and education. In the training department twenty-one blind persons had been admitted during the year, and at present fifty-six were being trained. The educational department now had students attending the University and the Provincial Training College to qualify as teachers. The Lord Provost, in moving the adoption of the report, said that the town council had a special interest in the work of the Royal Blind Asylum in virtue of the provisions of the Blind Persons Act of 1920. Last year the city had contributed over £2,000. The financial needs of the institution, however, tended to increase on account of the greater number under training, who came from all parts of Scotland. The directors were at present considering the question of providing a residential home for blind women, for which the need was very urgent.

The annual report of the Scottish National Institution for Blinded Sailors and Soldiers shows that since the institution was founded in 1915 no fewer than 101 blinded ex-service men had been already settled in life, and 30 more were in training. The Lord Provost, who presided at the annual meeting on June 23rd, drew attention to the fact that admissions are still being made and that there is no likelihood of these ceasing in the near future. The after-care men were doing well, some of them exceptionally well, as shopkeepers, boot repairers, poultry farmers, and in other trades to which they had been trained. The institution now owned seven houses with grounds attached, situated in various parts of Scotland, which were occupied by blinded men, and these small holdings were greatly prized by the occupants. These outside men were visited regularly by supervisors who were able to give them and their families help during illness and other occasions of necessity.

## TREATMENT OF RICKETS IN GLASGOW.

At the seventh annual conference of the Scottish National Association of Health Visitors, held under the chairmanship of Lady Leslie Mackenzie, Dr. Lewis Cruickshank of the Board of Health gave an address on the subject of ultra-violet ray treatment. He said that very favourable results had been obtained in tuberculosis and in rickets. Dr. Banks, medical officer of

<sup>1</sup> K.F. 20/26. *Fire Precautions at Hospitals*. London: George Barber, 23, Farnival Street, E.C.4. Price 6d. net, post free.

health for Motherwell, described the use of the ultra-violet rays at the Carnegie child welfare clinic in the industrial area near Glasgow; the greatest and most important disease of children to be treated there was rickets, and the results obtained by this method had been very satisfactory. Many cases unable to walk had been able to do so after three weeks' treatment, and, in addition, the whole organism of the child had been enormously improved. Rickets was a huge problem at the root of the nutrition and well-being of the industrial population. Dr. Chalmers Smith of Glasgow said that the results achieved in Glasgow had been striking and even dramatic; the incidence of the disease in the city was so great that he thought it would be wise to treat every child as if it had rickets for a month or two before it reached the age of one year.

#### CAMPAIGN AGAINST CANCER IN GLASGOW.

The directors of the Glasgow Royal Cancer Hospital have issued an appeal for funds to purchase radium for use in inoperable cancer. The greater number of the patients in this hospital suffer from the malady in an advanced and inoperable stage; radiation can therefore be given a full trial. The new x-ray department of the hospital possesses the latest form of equipment for furnishing deep penetration rays and for the improvement of the general health of the patients, and a room for ultra-violet ray treatment from two arc lamps has been added. Small supplies of radium emanation are obtainable from the West of Scotland Radium Committee, and some encouraging results have been obtained. The cost of radium is stated at present to be about £750 a grain, and as 1 gram would be needed to meet the requirements this would involve an outlay of about £12,000, and it is for this amount that an appeal is now made. Contributions may be sent to the secretary of the Glasgow Royal Cancer Hospital, Mr. H. Muir Lawson, C.A., 156, St. Vincent Street, Glasgow.

#### GIFT TO THE INFIRMARY AND UNIVERSITY OF EDINBURGH.

At a meeting of the board of managers of the Edinburgh Royal Infirmary on June 21st it was announced that Lady Mary Anne Anderson had bequeathed to the Infirmary the property of Beechmount, a mansion house situated on Corstorphine Hill on the outskirts of the city. The furniture of the house and a sum of £5,000 were also offered to the institution, with the suggestion that the managers use or dispose of them as they might see fit, but that if practicable the mansion should be retained in the possession of the Infirmary to be utilized as a home for officers maimed or invalided in the great war, or for the dependants of such officers. Lady Anderson also left to the University of Edinburgh a sum of £5,000 to be used in assisting the studies of undergraduates attending the University.

#### EDINBURGH ROYAL INFIRMARY RESIDENTS CLUB.

The annual dinner of the Edinburgh Royal Infirmary Residents Club was held in the North British Station Hotel, Edinburgh, on June 25th. Dr. C. E. Douglas (Cupar) presided over a company of past residents numbering about a hundred. The usual toast of "The Residency" was submitted by the chairman, who in the course of his address gave interesting reminiscences of Lister, Joseph Bell, Syme, Spence, and other teachers in the seventies of last century, with whom he had been associated as a student and house-surgeon.

## Ireland.

#### ROYAL MEDICAL BENEVOLENT FUND.

The annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held recently at the Royal College of Surgeons, Dublin, with Mr. T. E. Gordon, M.B., F.R.C.S.I., in the chair. The report of the Central Committee set out that the number of grants awarded during the year was eighty-five, as compared with eighty-six in

the preceding year. The amount disbursed in grants was £1,747 11s. 8d., as compared with £1,755 in 1924-25. The statement of accounts showed that the income of the general fund was £2,390 11s. 10d., as compared with £2,097 1s. 6d. in the previous year. The British Medical Association sent £54 4s., collected through its organization. A further cheque for £50 has been received from the British Medical Association, making a total grant of over £100 to the funds since January last. Donations amounted to £31 10s.; the Irish Medical Association contributed £10, and the Dublin Clinical Club £5 5s. Two legacies were received during the year. The late Dr. William Hennessy of Galbally left the sum of £100 for the purpose of providing an annuity of £5, or whatever that sum invested will be found to produce, for the benefit of widows or orphans of medical men, to be called the "Hennessy bequest"; and the late Mrs. E. Thompson of Kingstown bequeathed £100 to the Fund. Thanks are expressed to Dr. T. Hennessy, T.D., and to Mr. Herbert Dudgeon, the executors of these respective estates, for the work entailed. These sums, together with a further sum derived from recovered income tax, have been invested in War Loan Five per cent. Stock, 1927-49, to round off the holding in that security to the even figure £4,000. The Osborne fund being still in debt to the general fund, no grants have been charged against it; the debt has now been reduced to £4 8s. 2d. In concluding its report the committee points out that "while receipts from dividends and interest during the past year amounted to £1,079 4s. 11d., our normal subscriptions income was but £646 2s. 6d., a rather remarkable contrast between the contributions of the dead and of the living. We recognize with gratitude the liberality of those who subscribe, but we deplore the fact that so many contribute nothing. Could the mass of the profession but realize how much the grants of the society mean to the recipients—comforts otherwise beyond their reach, clothes for themselves or for their children, and in some cases the very essentials of life itself—we cannot but believe that the number of our supporters would materially increase. We therefore ask those who know the society's work to canvass their colleagues who are not subscribers so that the field of support may be extended and the financial stability of the Fund increased."

#### LONGER AND BETTER MODERN LIFE.

Dr. A. Trimble, chief tuberculosis officer, Belfast, in a recent address at Portrush, on some factors which have led to better health and the prolongation of life in the community, said that the improvement was best proved by a consideration of the general death rate. Taking Belfast as an index, the average death rate during the years 1890-94 was 25.9 per 1,000, while for the years 1920-24 it was 14.9 per 1,000, a reduction of 42 per cent. The death rate from tuberculosis in the same periods showed a reduction of 62 per cent. The reduction applied to practically all fatal diseases with the exception of cancer, which seems to be increasing, and of pneumonia, which was the general expectancy of life for the years mentioned, it would seem that thirty years ago at birth the expectation of life might be considered to be 33.6 years; at present it was 49.2, an addition to the average expectation of life of fifteen years. Dr. Trimble dealt with the ravages of plague, small-pox, and typhus some centuries ago, and said that the amount of time lost off work through disabling sickness was much shorter now than thirty years ago. When the causes of death in Belfast were analysed it was found that preventable infection and preventable infantile diseases had been accountable for at least 50 per cent. of the total deaths. In discussing the methods by which such avoidable waste of life might be prevented, Dr. Trimble emphasized the importance of cleanliness as a bulwark against infection, and of proper and adequate nourishment in enabling the body to resist disease. He advocated a reorganization of the educational system whereby greater facilities would be provided in elementary schools for personal cleanliness and for obtaining a knowledge of the facts which concerned health and life.

## Correspondence.

### TUBERCULIN IN THE TREATMENT OF TUBERCULOSIS.

SIR,—In the review of Dr. Camac Wilkinson's recently published book, *The Principles of Immunity in Tuberculosis*, which appeared in the *JOURNAL* of June 19th (p. 1039), no opinion is expressed as to the merits of tuberculin as a diagnostic and therapeutic agent in cases of pulmonary tuberculosis. After giving Dr. Wilkinson's high opinion of it in both respects it is said, "A very different verdict has been pronounced and is widely accepted." Unfortunately, this statement is true. But it does not follow that the very different verdict is the correct one. In my opinion it has been pronounced by people who have used tuberculin wrongly, and widely accepted by others who have not used it at all.

Wrong use of tuberculin is of two kinds: (a) keeping to minute doses (which have no apparent effect on pulmonary tuberculosis) through fear of producing reactions; and (b) increasing the doses by some rule of thumb, instead of adapting the rate of increase to each patient.

It is desirable that those who have extensive experience of the use of tuberculin in pulmonary tuberculosis, and who have taken the trouble to follow up their patients and keep accurate records, should now come forward and make known the results of their experience. I therefore venture to give my own experience in regard to some of the propositions from Dr. Wilkinson's book quoted in the review.

I. "Tuberculin is an invaluable and indispensable agent in the diagnosis of early tuberculosis." Tuberculosis dispensaries were opened in county Down in January, 1913. In all cases of suspected tuberculosis that have come for examination to these dispensaries, if tubercle bacilli were not found in the sputum, the tuberculin test by subcutaneous injection has been applied. Six doses are given with negative result before the case is pronounced non-tuberculous. When the six doses have produced no reaction I have great confidence in assuring the patient that he, or she, is not suffering from tuberculosis. This, of course, does not imply that the person cannot subsequently suffer from tuberculosis. In my experience of thirteen years as chief tuberculosis officer for county Down, about 1 in 80 of the patients thus entered as non-tuberculous have afterwards been found suffering from tuberculosis—usually several years afterwards. Of those who were classed as tuberculous because they reacted to the test doses, the symptoms and signs pointing to the lungs as the seat of disease, and who then received at least three months' tuberculin treatment, nearly all made a good recovery.

II. "Pulmonary tuberculosis can be cured with certainty by tuberculin." This statement needs some qualification. According to my experience it is true, or very nearly true, in the cases referred to above, where the diagnosis of pulmonary tuberculosis has been decided by test doses of tuberculin given subcutaneously, if the physical signs be such that the case can be classified as Turban-Gerhardt 1 or 2. Of all such cases diagnosed in the three years 1913-15 by me or my assistants, 86.5 per cent. were alive and at work, or fit for work, in March, 1926. Cases in which there were no physical signs, which I label T.G. 0, are not here included. In cases classed as T.G. (Turban-Gerhardt) 1 or 2, in which tubercle bacilli were found in the sputum, the prognosis is not nearly so good; but the results are in favour of tuberculin treatment, as will be seen from the following table:

Table showing the percentage fit for work in March, 1926, of cases diagnosed as pulmonary tuberculosis in 1913-15.

| (T.G. 1 or 2. Tubercle bacilli in all cases.)                                      |                |
|--|----------------|
| Treated with tuberculin at dispensaries at least three months; not at a sanatorium | 30.4 per cent. |
| Treated in a sanatorium at least three months; not treated with tuberculin ...     | 11.1 per cent. |
| Treated at neither sanatorium nor dispensary                                       | 4.3 per cent.  |

III. "The use of tuberculin in proper doses as a diagnostic agent is entirely free from danger." With this statement I am in thorough agreement.

IV. "Treatment by tuberculin in many cases allows the patient to attend to his ordinary calling, and has therefore a decided economic advantage." This is also in accordance with my experience.

I can hardly agree with Dr. Wilkinson on one point, however—namely, that "three months' training, notably at a tuberculin dispensary," is necessary for medical practitioners who desire to use tuberculin in the treatment of pulmonary tuberculosis. In a little book on the subject which I published in 1918 I laid down directions by which any intelligent person can estimate how to regulate the dosage in any particular case. When I get a new assistant who has had no previous experience of the use of tuberculin, I put this little book in his hands and tell him to read and re-read it carefully. Then I get him to accompany me to our dispensaries for a week or so, after which I usually find that he can be trusted to carry on by himself.

Several general practitioners in county Down now employ tuberculin treatment in domiciliary cases, pulmonary as well as non-pulmonary, under my direction, with benefit to their patients, using the little book and occasionally asking for guidance.—I am, etc.,

JOHN R. GILLESPIE, M.A., M.D., D.P.H.

Knock, Belfast, June 22nd.

SIR,—Tuberculin has been used as a therapeutic agent in the Dorset County dispensaries since 1914. The cases are for the most part pulmonary, but it is also now and then given to non-pulmonary cases.

It is given on the lines advocated by Dr. Camac Wilkinson—namely, the intensive method, which starts at extremely minute quantities of P.T.O. tuberculin and finishes off, if possible, at 1 c.cm. old tuberculin, human. A few cases are even carried on to bacillary emulsion (B.E.).

The success of this treatment depends on three most important conditions—namely: (1) the earliness of recognition of the onset of disease and freedom from secondary infections; (2) the careful technique and skill of the administrator in properly timing his doses, gauging them according to the strength reserves of his patient, and always avoiding making any overdraft thereon; (3) the conscientious co-operation of the patient himself. This is a *sine qua non* for success, but, alas! too often not obtained. In giving test-dose inoculations, the preparation known as T.A.F. tuberculin is given in preference to old tuberculin.

In my opinion all doubtful cases should be tested, for tuberculin demonstrates, like nothing else, the disease in its earliest stage. Even where the test conditions are not fulfilled a tuberculin sensitiveness may show an equally tuberculous susceptibility calling for suitable prophylaxis.

The great majority of pulmonary patients quite easily tolerate the initial doses of P.T.O. The few who cannot usually show their idiosyncrasy very soon and are then given some other form of treatment. The same may be said of secondarily infected cases. Those of the first class, however, equally soon show improvement, and, moreover, feel it. The delicate, peaky look becomes altered to a harder and more natural expression. The sputum is at first increased in quantity, may possibly have a streak or two of blood in it, and it may then be possible to find tubercle bacilli for the first time. One noticeable effect of this is that the cough, which has been hacking and incessant, becomes greatly relieved. In favourable cases, as the course proceeds, the cough and sputum gradually lessen, the pulse slows down and the temperature runs more evenly. It is at this stage that repeated warnings have to be given to some patients, who foolishly think they are sufficiently well to relax care and precaution. As often as not the result is a bad set-back for the patient and a disappointment to the physician. The danger of this, however, decreases with the increasing tolerance of the bigger doses of tuberculin. In fact, a case that has completed the course and reached 1 c.cm. of O.T. seldom causes me much anxiety if I know that he is carefully regulating his life. His acquired immunity, in fact, is always working on his behalf.

Personally I am convinced that the intensive tuberculin administration so alters the general system as to check the advance of tuberculous disease, and that this checking

power is proportionate to the degree of tuberculin immunity obtained. This process of immunizing the system against tubercle is in principle not different from the prophylactic inoculations against other diseases, save that we are dealing with a much more powerful toxin, and more care is therefore necessary in giving it. Its very potency, however, better lends itself to stimulating the body cells to antibody formation and therefore to a more lasting endurance thereof. Indeed, in the present state of our knowledge, it is difficult to see what other method can or will be employed for this purpose, so like is it to Nature's own method.

In conclusion I am tempted to say something about tuberculin prophylaxis.

If tuberculin can help a patient to throw off the disease by the raising of his body resistance, why should it not be possible to raise adequately the resistance of anyone who has only the tuberculous diathesis before he is attacked? Indeed, it is sometimes difficult to tell where diathesis ends and the disease begins. I am of opinion that herein lies the greatest value of tuberculin, in that it will be found to prevent the onset of tuberculosis in the same way that immunizations are secured against other diseases. I have noticed how well sickly, pretuberculous children tolerate tuberculin and improve in health. Some conclusions can be drawn from these cases in saying how long this artificial immunity lasts.

I do not wish to give the impression that every case does well or that the tuberculin course is always smooth sailing. It is often full of difficulties and set-backs, according to the complicating circumstances of the patient's life, and the physician has to exercise the utmost care in overcoming these opposing forces. It must be confessed that in not a few cases he fails. Nevertheless, when it can be given, there is, in my opinion, nothing to equal it in value. It seems to make the body put up a better fight and to hold more stubbornly the front line against the advance of tuberculous disease than anything else.—I am, etc.,

County Offices, Dorchester, June 28th.

H. C. MANNING.

### THE SPAHLINGER TREATMENT.

SIR,—Pace Dr. Jenkins (BRITISH MEDICAL JOURNAL, June 26th, p. 1103), I have never suggested that the memorandum issued by the Science Committee professes to "favour" the Spahlinger "remedy." What it does "favour" is a trial of the "remedy" under approved conditions. The difference between the two positions is a wide one, though Dr. Jenkins does not seem to appreciate it.—I am, etc.,

London, W., June 29th.

C. O. HAWTHORNE.

### POST-ENCEPHALITIS LETHARGICA.

SIR,—With reference to the correspondence on our paper entitled "Hyoscine in post-encephalitis lethargica" we would like to point out that Dr. W. S. Dawson has interpreted our views correctly in assuming that we used the term "hysterical" as synonymous with "functional." We note with interest that Dr. Dawson's experience of psychotherapy in these cases coincides with ours.—We are, etc.,

P. K. McCOWAN,  
J. S. HARRIS,  
S. MANN.

West Park Mental Hospital, Epsom, Surrey,  
June 26th.

SIR,—Dr. Moll's advocacy in the JOURNAL of June 26th (p. 1079) of the treatment of post-encephalitic Parkinsonism by nicotine has interested me greatly, and because it is important I may perhaps be pardoned for drawing attention to some points in the action of the drug.

He ascribes the benefit obtained to depression of the sympathetic pre-spinal reflex are subserving plastic tone. It has been shown by Langley that nicotine acts on the peripheral ganglion cells of the autonomic system and not on the preganglionic fibres, for the action may be obtained after these have degenerated. Further, the action is one

of transitory stimulation followed by depression of these cells, and clear evidence of this stimulation may be obtained from the preliminary fall in pulse rate which Dr. Moll describes, a change which must be due to stimulation of the parasympathetic cardiac ganglia.

A rather more important action of nicotine is the pronounced stimulation of the medulla and spinal cord, the case histories of which action may be obtained from the case histories reported. Since the increase in plastic tone is in the nature of a "release phenomenon," this stimulation is worth some consideration. Lastly, may I amplify Dr. Moll's account by drawing attention to the fact that nicotine is a very poisonous substance, nearly as toxic as prussic acid, and therefore care is necessary in its use?—I am, etc.,

University of Edinburgh, June 28th.

G. A. MASSON.

### ASEPTIC RESECTION OF THE COLON.

SIR,—The report of the proceedings of the Subsection of Proctology of the Royal Society of Medicine (JOURNAL, June 19th, p. 1050) leads me to suggest that surgeons should try using the crushing clamp hot, instead of cold (or warm). Thus used subsequent haemorrhage is much less likely to occur. Straight from the ordinary boiling sterilizer is possibly hot enough, but I have tried making it still more so in a flame. This must not be overdone, though, or the tissues will splutter and splash through violent boiling of the moisture in them.

A clamp heated by boiling water may easily be too hot for the surgeon's hands, and so require to be held in a towel; and, of course, care must be taken not to touch the wrong tissues with it.—I am, etc.,

Doncaster, June 24th.

W. REGINALD WILSON.

### REORGANIZATION OF THE UNIVERSITY OF LONDON.

SIR,—It is obviously you who are angry, not I. You have strenuously supported the removal of the University to the Bedford site; I have strenuously opposed this scheme since its inception by the Haldane Commission in 1911, because of the conditions implied in their report; the scheme has now definitely and finally failed after fifteen years of conflict. I leave it to your readers to judge which of us two has reason to be complacent.

Indeed, you are so angry that you most unpardonably misrepresent the facts of the offer of the site. The site was not "a gift" at any time, but was offered in exchange for property, the greater part of which is in the possession of King's College; after anxious, and certainly prolonged, deliberation, King's College refused to give up its part of the property, so coveted by the Government, and could not be compelled to do so. The Senate consequently notified the Treasury in June, 1925, that the *exchange*, insisted upon by successive Chancellors of the Exchequer, could not be effected. But it also expressed its eagerness to receive the whole, or any part, of the Bloomsbury site, as a gift for University purposes. The Treasury took no notice of this intimation for several months; until, in fact, their option upon the Bedford land had expired, and the gift, asked for by the Senate, was no longer feasible. I leave it again to your readers to judge whether these facts support your statement that the gift (?) of the Bloomsbury site was contumeliously rejected by the University.

You seem to suggest that the only friends I have in opposing the appointment of a departmental committee and its renewed attempt to revolutionize the constitution of the University are the Duke of Bedford's trustees. Why these irrelevant and innocent persons should be dragged into the argument I do not understand—the departmental committee expressly avoided any recommendations concerning the site. You must be unaware of two facts which sufficiently refute your suggestion. First, a resolution was passed, without a dissentient voice, at a record meeting of Convocation held on October 14th, 1924, with 809 members present:

"That this House protests against the appointment of a departmental committee on matters connected with London University, and further against the omission of any representative of Convocation from its personnel."

And secondly, at a special meeting of the Senate on October 9th, 1924, a resolution containing the following words was passed unanimously:

"The Senate is of opinion that such changes in the organization of the University, as are necessary, may be more readily effected by amendments promoted by the University than by a statutory revision of the University as constituted by the Act of 1898."

I think I may therefore claim that my position, in which you regard me as being solitary, is the position of both the Senate and of Convocation, who by statute have the final claim to speak for the University as a corporate body.

The Universities of Oxford and Cambridge were left undisturbed for about a century prior to the recent Statutory Commissions which have reported upon them. The University of London within the last forty years has suffered no less than three Royal Commissions and two departmental committees. Is there any reason to suppose that the present departmental committee, with its reference indicating that its inquiry was to be based upon the Haldane report, has found finality of wisdom as compared with its predecessors, so recent in time, so much more impartially constituted, and without any restriction of reference to a gravely discredited report?

In conclusion, since you compare the three Universities—Oxford, Cambridge, and London—it may interest your readers to know that the relative number of graduates upon the parliamentary roll for these three Universities is: Oxford 11,339, London 11,997, Cambridge 16,621. London in this respect has thus already passed Oxford and is rapidly overtaking Cambridge. It will also probably interest your readers to know that, of the 376 Fellows of the Royal College of Physicians of London, who are elected for professional distinction from its members scattered all over the world, 149 are graduates of London University, 97 of Cambridge, and 51 of Oxford. These facts, I submit, do not seem to justify your criticism that the University has mismanaged its affairs while it has had control of them. In size and in prestige it has made the most astonishing progress, notwithstanding the continual turmoil engendered by these too frequent interferences with its constitution.—I am, etc.,

E. GRAHAM LITTLE.

House of Commons, June 25th.

### THE ELECTRICAL TREATMENT OF TIC-DOULOUREUX.

SIR,—Dr. W. J. Turrell's communication on the electrical treatment of tic-douloureux (June 12th, p. 989) is a step forward to the understanding of a disease of still doubtful pathology, and it supplies a valuable therapeutic contribution.

His reference to the statement of a surgical colleague is perhaps a little severe. I remember the article well to which he refers, and my only criticism of it is that the Hartley-Krause operation is obsolete, as there are safer and simpler routes of approach to the ganglion and its immediate connexions. In my recent paper on the radical treatment of trigeminal neuralgia, published in your issue of May 8th and 15th, I omitted to state that I had employed the constant current in the treatment of the post-operative paraesthesias that arise. The result has been immediate, and I shall certainly employ it for subsequent cases.

Dr. Turrell's results will be gratifying to all readers, though a careful study of the reports of his cases does not convince me that the constant current alone is curative. If tic-douloureux is a sympathetic phenomenon, as I firmly believe, then the constant current is a most valuable palliative, as it is in arteriospasm elsewhere. But does it cure? I think the complete cure of tic, in the light of our present knowledge, is the combined task of the electrotherapist and surgeon. I have looked for some communication from the electrotherapist in connexion with the treatment of angina pectoris.

Electrotherapy as a remedial measure for those troublesome post-operative intestinal symptoms associated with pylorospasm of infants has yet to prove or disprove its

value. These troublesome and difficult symptoms, considered by many to be infective, are, I am sure, vegetative in origin and are only part of a general vegetative unbalance.—I am, etc.,

BASIL HUGHES, D.S.O., F.R.C.S.

Bradford, June 14th.

### RECOVERY AFTER MASSAGE OF THE HEART.

SIR,—In his article on recovery after massage of the heart in the *BRITISH MEDICAL JOURNAL* of April 24th, Mr. Girling Ball attributes his patient's recovery to massage of the heart, ignoring his own significant admission that 10 minims of adrenaline were injected into the heart muscle. It appears to me that the recovery may have been at least partially due to the latter procedure, as certain features of his case (very rapid pulse and extreme restlessness) so curiously resemble the case I relate below.

A Hindu boy of 15 was operated on by me at the Nasik Civil Hospital in June, 1924, for resection of a rib. The anaesthetic given was chloroform; early in the operation he stopped breathing. I immediately passed my left forefinger over the back of the tongue to ensure a clear airway, and at the same time a few motions of artificial respiration were carried out, but the boy remained pale and flaccid; he was then found to be pulseless and no heart sounds could be detected. Ten minims of adrenaline 1 in 1,000 were immediately injected into the apex of the heart through the fourth space, and artificial respiration continued. Within two minutes pulsation was visible in the neck, the heart beat became more and more rapid, and respiration returned. The operation was postponed, and the boy carried on a stretcher at once to the ward for restorative treatment. In a few minutes he had become acutely maniacal, shouting out and throwing himself about the bed. His pulse was counted several times in the neighbourhood of 190, and in spite of digitalin did not fall till next day, when he was very apologetic for being so noisy!

An operation was done later under cocaine, and he left the hospital "relieved" some weeks later.—I am, etc.,

W. C. SPACKMAN, M.B., B.S. Lond.,

Major, I.M.S.,

Civil Surgeon and Superintendent, Medical School, Ahmedabad, India.

May 19th.

### OBSTETRICS IN GENERAL PRACTICE.

SIR,—The letter of Dr. James Cook in the *BRITISH MEDICAL JOURNAL* of June 26th (p. 1101) leads me to ask what Dr. Kerr has to say to the following extract from the 1925 report of the Coombe Lying-in Hospital, Dublin, as reported in your issue of June 19th (p. 1059).

"The morbidity rate was 4.5 per cent. (32 cases). . . . In 24 of these patients no vaginal examinations were made, there was no laceration of the perineum, and no operative intervention necessary."

And is it in midwifery only that "young and inexperienced men" muddle along?—I am, etc.,

J. C. L. DAY.

Rhyl, June 26th.

### ATOPHAN DERIVATIVES IN RHEUMATISM: A CAUTION.

SIR,—On page 90 of the *Epitome* in your issue of May 29th the successful treatment of rheumatism and gout by injections of atophanyl is referred to. Certainly it is stated that not more than twenty injections should be given, but I should like to utter a caution on the subject of atophan derivatives. I have had personally two fatal cases of toxic jaundice following the use of atoquinol in rheumatoid arthritis, and I know of several others. The similarity between the symptoms in these cases and in those hepatic toxæmias produced by other ring compounds suggests that this is more than a coincidence. I hope that further data of these cases will be published later, but it has been suggested to me that I ought to call attention to the subject at once, so that we may be on our guard. It would be interesting to know if others have had similar unfortunate experiences.—I am, etc.,

W. LANGDON BROWN.

London, W., June 28th.

## Universities and Colleges.

## UNIVERSITY OF OXFORD

## Honorary Degrees.

At the Encaenia on June 23rd, presided over by the Chancellor of the University (Viscount Cave), a number of distinguished persons were presented for honorary degrees in the Sheldonian Theatre. Two of the recipients were medical men. The degree of D.C.L. was conferred on Lord Dawson of Penn, G.C.V.O., M.D., physician to the London Hospital; and that of D.Sc. upon Sir Walter Morley Fletcher, M.D., F.R.S., secretary of the Medical Research Council. According to custom each of the honorary doctors was presented to the Chancellor by the Public Orator, Mr. A. B. Poynton, M.A., Fellow of University College. The Latin text of the speeches with which Lord Dawson and Sir Walter Fletcher were introduced is printed below, and we are much indebted to the Public Orator for the English translations appended.

## Lord Dawson of Penn.

Adest vir artis medicae peritus, et quidem Regis ipsius e medicis, qui inter Londinenses per totam vitam et clinica diligenter exercenda et morbis hominum investigandis, praeceae Menenii sapientiae haud immemor, insignem laudem meruit. Idem ut in Gallia militum valetudinarius a belli principio impigre operam navavit, ita docendo, scribendo, praelegendendo etiamnum artis medicae studia illustrat. Nuper inter proceres adlectus unus ex Aesclepiadis Eupatridarum consiliis interest. Nos academici haud ignari sumus quantum referat malorum principii obstrare. Senectore tam prudenti, moderato, erudito confisi speramus fore ut progenies nostra, legum auxilio corroborata, ex tertio gradu pumilionum ad summum gradum Milonum evadat. Praesento vobis virum honoratissimum qui publicae sanitati sanam doctrinam adhibet, Bertrand, Baronem Dawson de Penn, illustrissimum ordinum Balnei et SS. Michaelis et Georgii Equitem Commendatorem, necnon illustrissimi ordinis Victoriani Magnae Crucis Equitem Commendatorem, ut admittatur ad gradum Doctoris in jure civili honoris causa.

[This is an eminent Physician, indeed one of the King's Physicians, who, not forgetful of the wisdom of old Menenius, by a life spent in London in the diligent practice of clinic and the investigation of human disease, has won distinguished honour. From the beginning of the War he rendered active help to the military hospitals in France, and even to this day he continues to add distinction to medical studies by teaching, writing, and lecturing. He has lately been called to the House of Lords, and is the only member of the guild of Aesculapius among the Peers. We, members of the University, know well how important it is to stop mischief at the beginning. We trust that by the help of a senator so wise, tactful, and learned, the population of our country, with a tonic of sound laws, may rise from the third grade of pygmies to the highest grade of athletes.\* I present to you one who applies sound learning to national health, the Right Honourable, Bertrand, Baron Dawson of Penn, K.C.B., K.C.M.G., G.C.V.O., that he may be admitted to the honorary degree of Doctor in Civil Law.]

## Sir Walter Fletcher.

Sequitur tertius Cantabrigiensis, rerum naturae indagator, qui periclitantibus accuratissime factis exposuit quas vices in animalium corpore elementa mutant, cum muscoli conducuntur, languent, alimentis recreantur. Cum juvenis olim et pedum pernecitate et mentis viribus insignis fuisset, multas et insignes partes in Academia et Collegio omnium magnificentissimo peregit, procurator, praelector, morum studiorumque moderator. Tum, cum ad summam dignitatem in Biochemia profundera pervenire potuisset, ultro se patriae ad munus gravissimum suscipiendum obtulit. Exquisitoria artis medicae studia propagantibus accessit hortator animosus, administrator prudentissimus. Nec tenues rivos ex immensis illis pecuniis quas viri magni ad levandos aegros legarunt, ad nos Oxonienses deduxit. Si monumentum benevolentiae quaeritis qua sororculam suam, Academiam nostram prosequitur, ad Parcum via patet; jamque regiae molis architectus supremam manum imponit. Itaque praesento vobis virum animi magnitudine et abstinentia insignem Walterum Morley Fletcher, illustrissimi ordinis Imperii Britannici Equitem, Regiae Societati adscriptum, Collegii Sanctae et Individuae Trinitatis inter Cantabrigienses socium, ut admittatur ad gradum Doctoris in scientia honoris causa.

[Here follows a third son of Cambridge, a researcher in Natural Science, who by most careful experiments discovered and expounded the chemical changes which take place when the muscles are contracted, grow weary, and are revived by nourishment. As an undergraduate he was remarkable not less for speed of foot than for force of mind, and he played many parts with distinction, both in the University and in his own most magnificent College, as Proctor, Lecturer, and Senior Tutor. Then, when he would certainly have risen to the highest honours in Biochemistry, as Professor, he offered his services to the country in a most responsible position. He became Secretary of the Council of Medical Research, and was both a spirited adviser and a wise administrator. By no means slender are the streams which he has diverted to Oxford from those splendid funds which great men have bequeathed for the relief of human suffering. If you

seek for evidence of his kind feeling towards his little sister of Oxford, the way to the Park lies open, and the architect is just putting his finishing touch to the kindly edifice. And so I present to you one who is eminent, both for the grandeur of his conception and his self-sacrifice, Sir Walter Morley Fletcher, K.B.E., F.R.S., Fellow of Trinity College, Cambridge, that he may be admitted to the honorary degree of Doctor in Science.]

Both Lord Dawson and Sir Walter Fletcher were also among the distinguished guests at the Gaudy held the same evening at Christ Church.

The Welsh Memorial prize for the study of human anatomy, and in particular of the art of drawing in relation thereto, has been awarded to R. E. Adam, scholar of University College. The work of J. C. L. Green, B.A., Balliol College, is highly commended.

## UNIVERSITY OF CAMBRIDGE.

At a congregation held on June 26th the following medical degrees were conferred:

M.D.—F. B. Smith.  
M.Chir.—T. M. Thomas.  
M.B., B.Chir.—N. T. Glynn, C. C. Halliwell, K. Fletcher-Barrett.  
B.Chir.—A. C. Copley, J. B. Ellison, F. W. Roques.

At a congregation held on June 29th the following medical degrees were conferred:

M.D.—F. A. Philipps, F. H. Young, C. H. Whittle, J. M. Smith.  
M.B., B.Chir.—L. P. Marshall.  
B.Chir.—F. A. Philipps, H. M. Woodman, J. A. S. Brown, H. B. Trumper.

\* Admitted by proxy.

## UNIVERSITY OF LONDON.

## Appointments and Resignations.

SIR WILLIAM BEVERIDGE, K.C.B., M.A., LL.D., B.C.L., Director of the London School of Economics, has been elected Vice-Chancellor for 1926-27, in succession to Professor E. A. Gardner, Litt.D. A cordial vote of thanks was passed to Professor Gardner for his services during his term of office.

The appointment of Dr. Major Greenwood to the University Chair of Epidemiology and Vital Statistics, tenable at the London School of Hygiene and Tropical Medicine, has been formally confirmed by the Senate. The foundation stone of the new home of the school will be laid by the Minister of Health at 3.30 p.m. on Wednesday next, July 7th, and though the school is in being it is not expected that the new building will be ready until the year after next. It is for this reason, presumably, that Dr. Major Greenwood has been appointed professor as from August 1st, 1926. While a member of the staff of the Lister Institute of Preventive Medicine Dr. Greenwood was appointed (January, 1915) Reader in Medical Statistics. In October, 1920, he was appointed a medical officer to the Ministry of Health.

Professor W. W. C. F. has been appointed to the University Chair of Bacteriology and Immunology at the London School of Hygiene and Tropical Medicine. He was Director of the Institute of Pathology at Charing Cross Hospital from 1911 to 1922, when he was appointed Professor of Bacteriology in the University of Manchester and Director of the Public Health Laboratories.

Mr. P. A. Buxton, M.A.Camb., L.R.C.P., M.R.C.S., has been appointed as from August 1st to the University Readership in Medical Entomology, tenable at the London School of Hygiene and Tropical Medicine. He graduated B.A.Camb. in 1914 (First Class, Natural Sciences Tripos, Parts I and II), and was a Fellow of Trinity College from 1916-21. From 1917-19 he was entomologist to the Mesopotamian Force, and from 1920-21 demonstrator in the zoology department at Cambridge. From 1921-24 he was medical entomologist to the Palestine Government and from 1924-25 leader of the expedition from the School of Tropical Medicine to the South Pacific. Since March, 1926, he has been Director of the department of medical entomology at the London School of Hygiene and Tropical Medicine.

The title of Reader in Pharmacology has been conferred on Mr. T. E. [Name obscured] in respect of the post of lecturer in [Name obscured] School of Pharmacy of the Pharmaceutical Society of Great Britain since 1920.

The resignations of Professor A. J. Clark from the University Chair of Pharmacology, tenable at University College, on appointment to the Chair of Materia Medica in the University of Edinburgh, and Dr. G. V. Anrep from the University Readership in Physiology, tenable at the same college, on appointment to a Lectureship in Physiology in the University of Cambridge, were accepted as from July 31st.

## Dunn Exhibition in Physiology.

The Dunn Exhibition in Physiology was awarded to Mr. G. G. Paine, an internal student, of St. Mary's Hospital Medical School, in the place of Mr. D. F. Ogborn, who was originally awarded the exhibition and has since been drowned in a boating accident while saving the life of another.

## LONDON HOSPITAL MEDICAL COLLEGE AND DENTAL SCHOOL.

On June 28th the Minister of Health distributed the prizes to students of the London Hospital Medical College and Dental School, and gave an address on the [Name obscured] research he made especial reference to [Name obscured]

\* Author of the famous parable about the belly and the members: cf. Livy, ii. 32, §§ 8-12.

\* Mulo of Croton: cf. Cicero, de Senectute, § 27.

with a view to ensuring the early detection of disease. More co-operation was required, and treatment to be complete must be a matter of team work. Professor William Wright, dean of the College, in presenting the annual report, said that during the year 553 students had been in attendance, 103 had taken medical or dental degrees or diplomas, and 39 had obtained post-graduate degrees or diplomas. He referred to the anonymous gift of £50,000 received during the year, which had been applied to the endowment of the Freedom Research Fund, the whole of the income being devoted to medical research. Lord Knutsford, proposing a vote of thanks to the Minister of Health, pleaded for greater support for the London Hospital, which would enable it to carry on more extensive research work. Lord Dawson, seconding the vote of thanks, said that it seemed to be inevitable that a large development in industrial medicine would come; employers would find it necessary to increase medical services for their employees in the interests of both parties, and the proportion of private medical work would diminish. There would also be an increase of clinics and hospitals in the future.

#### LONDON SCHOOL OF MEDICINE FOR WOMEN.

Sir John Ferguson, president of the Institute of Bankers, distributed, on June 25th, the prizes and certificates won by students at the London School of Medicine for Women, and addressed the students on the importance of the medical work to be undertaken by women. Lady Barrett, the dean of the school, who presided, gave a report of the very successful year that had passed, and anticipated even better results in the future. Out of twenty-five distinctions awarded by the University of London during the last twelve months, no fewer than eight had been won by students of the school.

#### UNIVERSITY OF DURHAM.

The following candidates have been approved at the examinations indicated:

M.D.—R. Mansoor, J. H. Saint (awarded gold medal), Margaret Scoresby-Jackson, E. A. Welsh, T. H. Blouch, C. R. Smith.  
M.D. *For practitioners of fifteen years' standing*.—V. P. Norman.  
M.B., B.S.—S. McD. Selby, H. Rosenbloom, G. Y. Fergetter, W. B. Allan, R. Y. Carter, M. Coll, A. D. W. Cooke, Dorothy E. Crisp, Mabel Dodds, Jessie S. Dunlop, F. P. Forrest, W. L. Falthorpe, H. Gass, H. D. Golder, R. A. Goodall, C. V. Harrison, Dorothy Hopkinson, J. H. Horsley, Grace O. Howie, D. S. Jackson, E. E. Kendall, R. A. W. Law, J. A. Livingston, G. M. Macintyre, F. McGuckin, G. P. McNabb, Grace E. McVitie, A. D. Miller, H. Moross, M. A. Phillips, Mabel Popham, R. H. Robinson, Phyllis Routledge, F. G. Sinclair, R. C. F. Smith, M. M. Sazman, Charlotte M. Thomson.  
The Philipson Scholarships have been awarded to S. McD. Selby and H. Rosenbloom.  
B.Hx. AND D.P.H.—Madge Hopper and G. Wilson.  
\* With second-class honours.

#### UNIVERSITY OF WALES.

The following students of the Welsh National School of Medicine have been approved at the examination indicated:

M.B., B.Ch.—D. J. Davies, T. E. Davies, Marjorie M. Duggan, Dilys Jones, D. R. Owen, H. G. St.M. Rees.

#### UNIVERSITY OF GLASGOW.

The following medical degrees were conferred on June 23rd:

M.D.—J. K. Rennie, G. M. Wishart, W. P. Grieve, W. K. Anderson, J. S. Bizett, D. Robertson.  
Ph.D. IN THE FACULTY OF MEDICINE.—A. McLeod Watson.  
\* With honours. † With commendation.

#### UNIVERSITY OF DUBLIN.

At a special meeting of the Senate of Trinity College held on June 29th the honorary degree of Master in Surgery was conferred on Sir Berkeley Moynihan, Bt., LL.D., F.R.C.S.

#### UNIVERSITY OF CAPETOWN.

At the graduation ceremony on July 3rd, 1925, the following were admitted to the degrees of M.B., Ch.B.:

G. F. Brown, G. H. G. du Toit, D. Epstein (with honours), Janet E. Masterton, B.A., J. S. Palm, S. Poyser, Elizabeth M. Reitz, J. D. K. Reitz, T. Richter, J. Smarth, R. E. Stevenson, R. V. S. Stevenson, J. H. Symington, D. R. Truter, F. D. J. Viljoen.

At the graduation ceremony on December 15th, 1925, the degree of M.B., Ch.B. was conferred on the following:

B. W. F. Bishop, F. A. Donnelly, G. F. Eagle, P. C. Eagle, H. P. Forster, J. A. P. J. Krutzinger, M. W. Mills, M. E. Pimstone, B.A., M. K. Tucker, G. F. van der Merwe, F. D. du T. van Zyl, D. H. R. Vollet, E. W. Watts, C. Weinberg.

At both ceremonies the degrees were conferred by the Vice-Chancellor, Principal Sir J. Carruthers Beattie, Kt., D.Sc.

The roll of medical students for 1925 shows the following numbers in each academic year; the number in parentheses indicates the corresponding total during the half-year ended December 31st, 1925:

|                 |           |                 |         |
|-----------------|-----------|-----------------|---------|
| First year ...  | 69 (54)   | Fourth year ... | 27 (24) |
| Second year ... | 63 (34)   | Fifth year ...  | 24 (26) |
| Third year ...  | 46 (42)   | Sixth year ...  | 29 (20) |
| Total ...       | 258 (200) |                 |         |

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

On his retirement from the Presidency of the Royal College of Surgeons in Ireland, Mr. Robert C. B. Maunsell has been presented with a salver by the members of the Council as a mark of their appreciation of the admirable manner with which he carried out the important duties of his office during the years 1924-25.

#### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SURGERY.—A. M. El-Mishad, W. E. Ivers, L. Schapera, A. D. Shubsachs, C. H. Spencer.  
MEDICINE.—E. A. Stroud.  
FORENSIC MEDICINE.—R. V. Cookes, J. E. Howard, D. Jacobson, R. Lamort, T. C. Pains, J. Patis, L. Schapera, E. A. Stroud.  
MIDWIFERY.—S. B. Browning, W. O. R. Fischer, J. H. Gillatt, M. N. Nicolson, M. Pettigrew, M. Stainesbeck.

The diploma of the Society has been granted to Messrs. R. V. Cookes, W. O. R. Fischer, J. E. Howard, R. Lamort, A. M. El-Mishad, M. N. Nicolson, M. Pettigrew, and A. D. Shubsachs.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

In the House of Commons this week the chief business has been the Coal Mines Bill, permitting for a period of five years an extension of the working day in coal-mines to eight hours. The Parliamentary Medical Committee met on June 30th to hear Mr. Wilfred Buckley, President of the National Clean Milk Society, and also two inspectors of the Ministry of Health, on the regulations about the use of preservatives and food-stuffs. These regulations come into force next January.

The report of the Select Committee on nursing homes has been drafted, and will be considered by the Committee on July 6th. Its issue is expected within a week thereafter.

#### Smoke Abatement Bill.

As briefly announced last week, the Smoke Abatement Bill, which has already passed through the House of Lords, was read a second time in the House of Commons, on the motion of the Minister of Health, on June 22nd. It had been formally read a second time in the House of Commons, but there seems to have been some irregularity and the vote was rescinded so that the Minister might explain the aims and objects of the bill. In so doing, Mr. Neville Chamberlain began by recalling that in 1920 a departmental committee had been appointed under the chairmanship of Lord Newton to advise what measures could be taken to mitigate the emission of smoke and other noxious vapours. The committee reported in 1921, and since then four bills had been introduced; that now before the House was more or less founded on its recommendations. Public opinion had progressed steadily during the past few years in the direction of demanding cleaner air. While this might be due to some extent to the introduction of the bills, it was still more the result of advances in medical knowledge and the recognition of the vitalizing effects of sunlight. Even now, he doubted whether those who habitually lived in towns fully realized the extent to which they were deprived of those essential factors. It was estimated that the people who lived in the country got 20 per cent. more sunlight than those who resided in towns. The emission of smoke must necessarily mean a waste of fuel. The Newton Committee declared that about 2,500,000 tons of soot escaped into the atmosphere every year in this country from domestic fireplaces, and another 500,000 tons from industrial works. That represented a very substantial sum. An inquiry made in Manchester in 1918 comparing the cost of washing in that town with the cost in Harrogate showed that the inhabitants of Manchester, in order to keep clean, had each to spend 7½d. more every week than the inhabitants of Harrogate. It was estimated that Manchester

100,000 more in washing in order to keep apart from the damage done by smoke it was only necessary to look round the buildings to see the effect of acid soot when it was deposited on even the most durable kinds of stone. The pollution of the atmosphere by smoke was at once costly, wasteful, and highly injurious to human health. When, however, they came to consider in what way the law should be amended in order to diminish this evil, differences of opinion began to arise, and this bill had not escaped criticism. Those who might be called smoke consumers thought that it was not sufficiently drastic and would do little to improve matters, while the smoke producers expressed the view that its provisions were so drastic as to be likely to cause serious injury to at any rate some of the industries of the country. He hoped that the bill was striking a happy medium, while he realized that at this moment, above all others, nothing should be done to add fresh obstacles to British industry. But he believed that a great deal could be done to prevent the emission of noxious vapours without doing any injury to industry. If he had not entirely succeeded in carrying out his intentions he would only be too happy to hear in Committee any representations which might be made. Mr. Chamberlain described the provisions of Clause 1 of the bill, which amended the provisions of the Public Health Act, 1875, relating to smoke nuisances, so as to include other kinds of smoke besides black smoke, and extended the definition of the

word "smoke" to include "soot, ash, grit, and gritty particles." The clause increased the penalties for the commission of offences so that it would be a serious matter for manufacturers to break the law. It was proposed to allow temporary exemption to certain processes which could not at present be carried on satisfactorily in this country without the emission of smoke. Though private dwellings were the greatest sinners, he did not think it wise to include them, since in the present stage of knowledge it would be too great an interference with private liberty. The solution of the smoke difficulty lay in two directions. One was to make it as easy and cheap as possible for people to use gas and electricity. The other was in the production of smokeless fuel. A section of the Department of Scientific and Industrial Research had for some years been investigating fuel and making tests for private individuals. Although the problem had not yet been solved, progress had certainly been made. If, in the course of a year or so, a smokeless fuel was obtained which could be used in the open grate and which was sufficiently cheap and practicable to commend itself to the ordinary man and woman, it might be possible to amend this bill and to allow local authorities to exercise control over the burning of raw coal in grates. Until that time came, however, it would be best to leave the matter where it stood.

Dr. Salter said that he gave a general support to the bill, but with no great enthusiasm. He was concerned at the numerous loopholes and opportunities for evasion. Any amendments accepted by the Minister of Health in Committee ought to strengthen and not weaken the bill. The two greatest scourges of working-class life to-day were chronic rheumatism and chronic bronchitis. These two groups of diseases caused a greater loss of working time than almost all the others put together. Tuberculosis was receding fast into the background as one of the great disabling influences in working-class life. The discovery that most forms of chronic rheumatism took their origin in dental sepsis had led to a great deal of dental attention being given under the National Health Insurance Act and in other ways for the prevention of chronic rheumatism, but practically nothing was being done for the prevention of chronic bronchitis. The figures of the Ministry of Health showed that these two groups of diseases were getting worse every year. Chronic bronchitis had been clearly traced to soot and dirt in the atmosphere, and he welcomed the bill in so far as it would mitigate these diseases.

Dr. Fremantle said that the Ministry of Health appeared to have the impression, which was growing outside as well, that fireplaces should be abolished. Personally, he did not agree. The open fireplace was superior to closed heating systems which prevailed in America and other places abroad, because it provided ventilation. It was also adaptable to the needs of the individual. He hoped that it would be possible to insert in the bill later on some provision giving local authorities power to see that grates in new houses were of a kind which conserved heat and consumed smoke.

The bill was read a second time.

#### Bills.

The Rag Flock Act (1911) Amendment Bill was read a second time in the House of Commons on June 23rd.

In the House of Commons, on June 28th, Mr. A. V. Alexander introduced a bill to amend the Dentists Act, 1921, and it was read a first time.

**International Information as to Tropical Diseases.**—On June 28th Mr. Amery said the Bureau of Hygiene and Tropical Diseases, the Imperial Bureau of Entomology, and the Imperial Bureau of Mycology constantly received from all parts of the empire and foreign territories information on the problems of tropical disease affecting man, animal, and plant. This information was summarized in the periodical reviews, published by these bureaux, and distributed to subscribers, including the Governments of the overseas dependencies. In research on human tropical disease valuable work was done by the health organization of the League of Nations, through which knowledge of the progress made in that direction was widely distributed between the different Governments represented in the League.

**Women Nurses for Male Insane Persons.**—On June 28th Mr. C. Edwards asked the Minister of Health whether he was aware that at the Hellingly Asylum the East Sussex County Council employed female nurses in attendance on insane male patients; and whether, in view of the moral and physical dangers thus involved, he would take steps to prevent this practice. Mr. Chamberlain said female nurses were so employed. He was unable to accept the assumption upon which the second part of the question was based. Medical superintendents who had had experience of the practice of nursing male patients by women nurses were practically unanimous in thinking that this was desirable in certain types of cases, and that no risk to the nurses arose. He did not, therefore, propose to take any action.

**Foot-and-Mouth Disease.**—In a reply, on June 16th, to Mr. W. Thorne, Mr. Guinness (Minister of Agriculture) said that in the instances of foot-and-mouth disease in imported carcasses of pigs which brought about the Order prohibiting the import of fresh meat from the Continent, lesions of foot-and-mouth disease were only found in carcasses which had not been scraped or scalded. Scraping and scalding might make the discovery of the lesions difficult, but the carcass would be capable of introducing the disease to this country. The Ministry of Agriculture had no evidence that Chinese pork was capable of disseminating foot-and-mouth disease in this country. Chinese pigs were imported in calico cloths which, under the Packing Materials Order of 1925, must be thoroughly sterilized before further use. The certificate of the United States Government accompanying "box" loins of

pork imported into this country provided all the necessary guarantees for safeguarding the public health. Answering Mr. Kennedy on June 17th, Mr. Guinness said that the Ministry of Agriculture inspected all imports of frozen meat, but not from the point of view of foot-and-mouth disease. There was no evidence that that disease could be conveyed in frozen meat. The danger was chiefly in the blood. They were taking steps with the Argentine Government to see that proper precautions were observed to prevent the slaughter and export of animals suffering from foot-and-mouth disease.

**Anthrax and Shaving-brushes.**—Mr. Chamberlain stated, on June 24th, that one case of anthrax caused by an infected shaving-brush had occurred this year. It was not fatal. Steps had been taken to deal with any future consignments of shaving-brushes from this source, and the matter had been referred to the Government of the country of origin for appropriate action.

**Puerperal Septicæmia.**—In reply to questions, Sir Kingsley Wood stated, on June 28th, that the report made by one of the medical officers of the Ministry of Health on the Kingston Nursing Association's home, where eight deaths from puerperal septicæmia had occurred during the last six months, showed that there had been grave laxity in administration and in the district midwifery practice associated with the home. He intended to address a communication to the Nursing Association and send copies to the County Council and the Kingston Town Council. In reply to Dr. Fremantle, who asked whether steps would be taken to ensure the speedy passage of the Midwives and Maternity Homes Bill, Sir Kingsley Wood asked for notice.

**Disinfectants on Merchant Vessels.**—The President of the Board of Trade has stated that disinfectants approved for use on board merchant vessels were submitted for approval and were tested chemically by the Government laboratory and bacteriologically by the Lister Institute. If they did not come up to the required standards they were not approved. The list of approved disinfectants was continually under revision, the officers concerned having been instructed to take samples from time to time. Where a sample was found not to conform to the required standard the name of the disinfectant was removed from the approved list. He would, however, have the list examined as suggested by Mr. Cluse.

**Veneral Disease in the Army.**—The Secretary of State for War has stated that during the last three years for which complete statistics were available the incidence of venereal disease in the army had decreased from 74 per 1,000 of the strength in 1921 to 47.8 per 1,000 in 1924. His medical advisers considered that this reduction was mainly due to the very effective preventive measures that had been and were still being employed.

**Insurance Funds.**—Mr. Chamberlain, in a reply to Sir Grafton Doyle, on June 24th, gave the following particulars concerning National Health Insurance in England and Wales: Total accumulated funds at December 31st, 1925, £113,000,000. Total payments made during the year ended December 31st, 1925: By insured persons, £11,970,000; by employers, £12,800,000; by the State, £7,220,000. Number of insured persons: Male, 9,395,000; female, 4,550,000. Total benefits paid during the year ended December 31st, 1925: For sickness benefit, £9,335,000; for disablement benefit, £4,514,000; for maternity benefit, £1,489,000; for medical benefit, £8,449,000; for additional benefits not included above, £761,000.

**Artificial Light Treatment.**—On June 28th Sir K. Wood told Captain Fraser that, according to the information in the possession of the Ministry of Health, provision had been made for artificial light treatment at, or in connexion with, maternity and child welfare centres in the following metropolitan boroughs: Bethnal Green, Islington, St. Pancras, Deptford, Kensington, Shoreditch, Greenwich, Poplar, Southwark, Hackney, St. Marylebone, Stepney, Westminster. Where the prior approval of the Ministry was obtained to the arrangements, and a contribution was desired, the usual grant of 50 per cent. was being paid towards the net cost of the installation and of the first year's running expenses.

**Driving Licences.**—Colonel Ashley, on June 24th, told Sir Gerald Strickland that the general question of the issue of driving licences to persons suffering from physical disabilities was under his consideration in connexion with the promised bill for the better regulation of road vehicles. Commander Kenworthy asked whether the Minister was aware that deaf men were extremely intelligent and had excellent sight. Colonel Ashley said that as he was slightly deaf himself he subscribed to this statement.

#### Notes in Brief.

The report of the Chief Inspector of Factories for 1925 cannot be issued before the end of this month.

The Minister of Health is advised that local authorities already have power under the Public Health Acts to deal with ponds, ditches, and other places where nuisance arises through the breeding of mosquitos. On the information at present available he doubts whether further legislation is required.

On March 31st last 13,663 blind persons in England and Wales between 50 and 70 were in receipt of old age pensions, under Section 1 of the Blind Persons Act, 1920. About 8,880 blind persons over 70 were in receipt of old age pensions under the Old Age Pensions Acts.

The Home Secretary hopes to introduce the bill to amend the Factory Acts this month.

From January to May, 1926, 734,132 cwt. of condensed skimmed milk were imported into the United Kingdom. The Minister of Agriculture is advised that the temperatures to which this milk was subjected at the factories did not suffice to destroy the virus of foot-and-mouth disease and the tubercle bacillus.

## The Services.

## MEDICAL BRANCHES OF THE SERVICES.

## IMPROVED TERMS AND CONDITIONS.

As a result of the recommendations of the Interdepartmental Committee on the Medical Branches of the Fighting Services, before whom the British Medical Association gave evidence early this year, substantial increases in the rates of pay and retiring gratuities, and improved conditions of promotion and retirement for officers of the Royal Army Medical Corps, Army Dental Corps, and the Royal Army Veterinary Corps, are embodied in a Royal Warrant issued by the War Office on June 29th (A.O. 196, 1926). A further Army Order revises the scales of pay and retired pay for the Army Nursing Services. Simultaneously the Air Ministry has announced improvements in the conditions of service and emoluments of medical officers of the Royal Air Force, and of members of the R.A.F. Nursing Service. The Admiralty also is issuing this week an Admiralty Fleet Order prescribing improved terms and conditions of service for medical officers R.N., dental officers R.N., and members of Queen Alexandra's Royal Naval Nursing Service. We understand that revised terms and conditions of service for officers of the Indian Medical Service are likely to be issued shortly.

The changes, generally, will take effect from July 1st, 1926, or (in the case of naval officers) "as soon afterwards as the necessary arrangements can be made." They were foreshadowed by the Prime Minister in his statement in the House of Commons on June 15th (reported in our issue of June 19th, 1926, p. 1063), that the Government had considered the report of the committee appointed last autumn to consider questions relating to pay and other matters affecting recruitment of medical officers and nurses in the medical branches of the fighting services, and had decided to give effect to the committee's recommendations as from the first day of this month.

## ROYAL ARMY MEDICAL CORPS.

The following table, extracted from the Army Order, contains the old and the new rates of pay for officers of the R.A.M.C. The revised rates are identical with those recommended by the British Medical Association in its Memorandum of Evidence.

| Old Rates.   |               | RATES OF PAY. |   | New Rates. |  |
|--|---------------|---------------|---|------------|--|
|  |               | £ s. d.       |   | £ s. d.    |  |
| Lieutenant ... ..  |               | 1 2 0         | Lieutenant ... ..                                     | 1 2 0      |  |
| Captain ... ..   |               | 1 7 0         | Captain ... ..  | 1 7 0      |  |
| Captain, after 6 years' commissioned service ...             | 1 8 0         |               | Captain, after 8 years' commissioned service ...      | 1 10 0     |  |
| Captain, after 10 years' commissioned service ...            | 1 11 0        |               | Captain, after 10 years' commissioned service ...     | 1 12 6     |  |
| Major ... ..   | 1 15 0        |               | Major ... ..  | 1 17 6     |  |
| Major, after 15 years' commissioned service ...              | 2 0 0         |               | Major, after 15 years' commissioned service ...       | 2 2 6      |  |
|  |               |               | Major after 18 years' commissioned service ...        | 2 5 0      |  |
| Lieutenant-Colonel ... ..                                    | 2 10 0        |               | Major, after 20 years' commissioned service ...       | 2 10 0     |  |
| Lieutenant-Colonel, after 20 years' commissioned service ... | 2 12 6        |               | Lieutenant-Colonel ... ..                             | 2 17 6     |  |
| Lieutenant-Colonel, after 25 years' commissioned service ... | 2 15 0        |               | Lieutenant-Colonel after 3 years' service as such ... | 3 2 6      |  |
| Colonel ... ..   | 3 5 0         |               | Colonel ... ..  | 3 10 0     |  |
| Major-General ... ..   | 4 15 0        |               | Major-General ... ..                                  | 4 15 0     |  |
| Director-General ... ..                                      | £2,500 a year |               | Director-General ... ..                               | 6 0 0      |  |
|  |               |               | (plus Lieutenant-general's allowances)                |            |  |

## Additional Pay.

An officer of the R.A.M.C., employed at the War Office as Assistant Director-General, Assistant Director, or Deputy Assistant Director-General, will receive additional pay at 5s. a day instead of 2s. 9d. as at present.

## Time in Civil Hospital Appointments.

An officer of the R.A.M.C. commissioned after holding a resident appointment of not less than one year in a civil hospital may be granted an antedate not exceeding one year in respect of the period spent in such an appointment provided that the interval between the termination of the hospital appointment and the date of entry into the service shall not ordinarily exceed six months. The antedate will count as commissioned service for the

purpose of increments of pay, promotion, retirement, retired pay, and retiring gratuities.

## Retiring Allowances.

An officer of the R.A.M.C. will be eligible to retire with a gratuity of £1,000 after seven years' service instead of after eight and a half years'. An officer of the R.A.M.C. who, after three years' service as a major is eligible to retire with a gratuity of £1,800, or after six years' service as a major with a gratuity of £2,500, will be eligible to retire with £2,800 in lieu of £1,800 and £3,500 in lieu of £2,500. An officer serving as a medical officer in the R.A.M.C. on September 13th, 1919, will be eligible on retirement as a major after twenty years' service for retired pay at a daily rate of £1 if more favourable to him than the rate assessed under the ordinary scale for medical officers. An officer who has retired as a major since September 13th, 1919, after completing twenty years' service shall be entitled to benefit under this provision with effect from the date of retirement.

In any case in which transfer from the rates of pay hitherto in force to the new rates involves a loss of emoluments, the officers may continue in receipt of the rates of pay hitherto in force until such time as, on account of increment or promotion, the new rates are equal to or exceed the old rates.

The revised rates of pay and additional pay (but not charge pay) sanctioned in this Warrant will be subject as from July 1st, 1926, to the deduction of 5½ per cent. which was made to the old rates as from July 1st, 1924, and will further be subject to revision in respect of subsequent variation in the cost of living, in the same manner and to the same extent as the rates introduced from July 1st, 1919.

## MEDICAL OFFICERS R.N.

The following are the revised terms and conditions for naval medical officers announced by the Admiralty.

**Increase in Establishment of Surgeon Captains.**—The maximum number of surgeon captains authorized to be borne will be increased from sixteen to twenty. Two surgeon captains will be appointed to the R.N. Hospital, Haslar, as Professors of Medicine and Surgery respectively, on instructional duties connected with the general courses described below. The appointment of Director of Medical Studies, Naval Medical School, R.N. College, Greenwich, will in future be held by a surgeon captain, and a surgeon captain will be appointed to the R.N. Hospital, Malta, as second in charge.

**Specialists' Allowances and Appointments.**—The number of specialist appointments will be increased from forty-six to sixty, and the new appointments will include specialist posts in Medicine, Surgery, Radiology, and Hygiene. The allowance payable to holders of specialist appointments will be increased from 2s. 6d. to 5s. a day, as from July 1st, 1926.

**Charge Pay.**—The grant of charge pay will be made as from July 1st, 1926, on the following scale for medical officers in charge of hospitals and sick quarters: Surgeon rear-admirals and surgeon captains 10s. a day; surgeon commanders 5s. a day.

## Professional Courses.

(a) **General Courses.**—Every officer below the rank of surgeon captain, except when he has just vacated an appointment at a home hospital or is due to take his promotion course, will be appointed, if his services can be spared, once in every four years to the R.N. Hospital, Haslar, for a course of instruction of not less than four months' duration in clinical medicine and surgery and allied subjects. At the end of the course, instead of being placed on unemployed time, the officer will be appointed for duty at one of the R.N. Hospitals at Haslar, Chatham, or Plymouth, unless or until he receives an appointment elsewhere.

(b) **Specialist Courses.**—Every officer selected to hold a specialist appointment will, provided his services can be spared, undergo a course of not less than six months' duration in his special subject at a civil hospital in London or other teaching centre, and will subsequently undergo a course of three months' duration in that subject every four years while he is employed as a specialist.

(c) **Senior Medical Officers' Courses.**—The existing senior medical officers' courses will to a large extent be superseded by the general and specialist courses described above, and their number will, therefore, be capable of reduction without detriment to the professional opportunities in the service, but the reduction will not be made until the new courses have been in operation for some years.

The institution of general and specialist courses will necessitate an increase in establishment, and they cannot therefore be put into full operation until this increase has taken place, but the new arrangements will be inaugurated as soon as possible.

## Time in Civil Hospital Appointments.

In the case of officers entering the naval service on or after July 1st, 1926, the following rules for counting time in hospital appointments will apply:

An officer who enters the Service on or after July 1st, 1926, and who has held, for a period of not less than one year before the date of his entry into the Service, a resident appointment as medical or surgical officer in a civil hospital after becoming a qualified medical practitioner, to be eligible, at the discretion of the Admiralty, to have his seniority antedated by not more than one year, provided that the appointment is one recognized by the Admiralty for this purpose, but this concession will not ordinarily be granted where the interval between the termination of the hospital appointment and the date of entry into the service exceeds six months. The period of not less than one year in a "resident" appointment may, at the discretion of the Admiralty, include a period of not more than six months spent in a "non-resident" appointment recognized by the Admiralty.

<sup>1</sup> The Memorandum of Evidence submitted by the Association was printed in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of January 30th, 1926, pp. 34-36.

The increase of seniority allowed under the above conditions will not render an officer eligible to receive pay before the date of his actual entry into the Naval Service, but the time concerned shall reckon for increase of full, unemployed, and half-pay while on the active list and retired pay or gratuity on retirement or withdrawal, provided, in the case of a gratuity, that the officer has completed three years' full-pay service in the Royal Navy—that is, exclusive of the time spent as resident medical or surgical officer in a civil hospital.

In the event of a temporary officer, or an officer entered for short service, being transferred to the permanent list on or after July 1st, 1926, he may be granted the above concession, at Admiralty discretion, under similar conditions to those applicable to candidates who may enter the permanent service direct, except that the time shall not count for gratuity on retirement or withdrawal.

A candidate who is over the normal age limits for entry may be entered, notwithstanding, provided that the period of antedate for which he is eligible brings him, if deducted, within the ordinary limits.

#### R.A.F. MEDICAL SERVICE.

The Air Ministry announces a number of improvements in the conditions of service and emoluments of medical officers of the Royal Air Force.

The communiqué states that the Air Council attaches great importance to attracting into the service the best type of medical man, since on the capacity of the medical service depends to a peculiar degree the safety and efficiency of the Air Force. The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed upon the aviator in diverse circumstances and climates. The work to be done, therefore, has a high professional interest, and, with the improved conditions detailed below, the Ministry hopes that applicants of the best quality will be forthcoming.

#### Short-Service and Permanent Commissions.

Entry into the medical branch is by means of a short-service commission for three years on the active list extensible to five years. Entry into the service, therefore, does not commit the entrant to a permanent career, but leaves him free to return to the civil profession and the service free to choose the best officers for retention. Permanent commissions are granted by selection to officers holding short-service commissions, and in order that all short-service officers who desire to remain in the service may have a reasonable opportunity of doing so it has been decided that so far as practicable every entrant shall have a 50 per cent. chance of a permanent commission. Further, in order to assist short-service officers who pass to the reserve after five years to set up in private practice the gratuity issuable on leaving the active list has been increased to £700, the gratuity after three years' service remaining at £350 as hitherto.

#### Increase of Pay.

Increases of pay of from 2s. to 11s. a day have been granted in all ranks above flight lieutenant, and the scale in force from July 1st, 1926, is shown in the following table. The rates in the first column are "standard," and are liable to the extent of 20 per cent. to periodic variation according to the cost of living. The current rates are shown in the second column, and in the third the total yearly emoluments at current rates if allowances are drawn in cash in lieu of provision being made in kind. The cash allowances included are at current home rates for unmarried officers. Married officers over 30 years of age receive higher allowances.

| Rank.                        | "Standard"<br>Rate of Pay<br>per Diem. | Current<br>Rate of Pay<br>per Diem. | Current<br>Rate of Pay and Allow-<br>ances per<br>Annum. |
|------------------------------|--|-------------------------------------|--|
| Flying Officer ... ..        | £ s. d.<br>1 4 0                       | £ s. d.<br>1 2 8                    | £557   |
| Flight Lieutenant ... ..     | 1 6 0                                  | 1 4 6                               | £603   |
| 1st Lieut. after 2 years     | 1 8 0                                  | 1 6 6                               | £545   |
| 1st Lieut. after 4 years     | 1 10 0                                 | 1 8 4                               | £578   |
| 2nd Lieut. after 2 years     | 1 14 0                                 | 1 12 2                              | £760   |
| 2nd Lieut. after 4 years     | 1 18 0                                 | 1 15 10                             | £327   |
| 3rd Lieut. after 2 years     | 2 0 0                                  | 1 17 10                             | £364   |
| 3rd Lieut. after 4 years     | 2 4 0                                  | 2 1 6                               | £351   |
| 4th Lieut. after 2 years     | 2 8 0                                  | 2 5 4                               | £1,001   |
| 4th Lieut. after 4 years     | 2 10 0                                 | 2 7 4                               | £1,037   |
| Wing Commander ... ..        | 2 15 0                                 | 2 12 0                              | £1,135   |

| Wing Commander after 4 years | 3 3 0                                  | 2 19 6                              | £1,270   |
| Major ... ..                 | 3 10 0                                 | 3 6 2                               | £1,465   |
| Air Commodore ... ..         | 4 0 0                                  | 3 15 8                              | £1,691   |
| Air Vice-Marshal ... ..      | 5 0 0                                  | 4 14 6                              | £2,103   |

Promotion to flight lieutenant occurs after two years' satisfactory service, and to squadron leader after ten years' service, reducible to eight years in exceptional cases. Promotion above squadron leader is by selection subject to minimum periods of service. The Director of Medical Services, if (as at present) an air vice-marshal, will receive the pay and allowances of his rank.

#### Retiring Allowances to Permanent Officers.

The gratuities issuable to permanent officers have been increased to £1,500 after ten years' service, and £2,500 after fifteen years' service. After twenty years' qualifying service officers are eligible for retired pay, the amount depending on age and length of service, and in the case of senior officers on rank. The maximum rates of retired pay are, subject to certain conditions, as follows, the rates for air commodores and air vice-marshals being new:

| Rank.                   | "Standard"<br>Maximum Rate. | Current<br>Maximum Rate. |
|-------------------------|-----------------------------|--------------------------|
| Air Vice-Marshal ... .. | £1,010                      | £954 10s.                |
| Air Commodore ... ..    | £950                        | £893                     |
| Group Captain ... ..    | £900                        | £850 10s.                |
| Wing Commander ... ..   | £800                        | £767                     |
| Squadron Leader ... ..  | £500                        | £472 10s.                |

#### House Appointments in Civil Hospitals.

To attract into the Service graduates who have had the valuable experience provided by a hospital appointment it has been decided, subject to certain conditions, to allow doctors who have held a resident appointment in a recognized civil hospital for not less than one year—of which, however, half may have been spent in a non-resident appointment—to enter the Air Force with one year's antedate counting for purposes of seniority, promotion, retired pay, and retiring gratuity. Service pay will not be issuable for the period spent in a civil hospital nor will the time count towards the gratuity payable to short-service officers on transfer to the reserve.

#### Course of Instruction on Entry.

Every officer on entry will in future receive eight weeks' instruction in the medical problems connected with flying and in his other Air Force duties.

#### Opportunities for Professional Study.

With a view to enabling permanent medical officers to take at least one general or specialist course at a civil or a service medical school it has been decided to allow study leave up to nine months in all to officers during the first sixteen years of their service. So far as possible officers will be allowed such leave when convenient to themselves, and their wishes as to the choice of subject and place of study will be consulted.

#### DIRECTOR-GENERAL A.M.S.

THE War Office announced on June 25th that Major-General Sir Matthew H. G. Fell, K.C.B., C.M.G., has been appointed Director-General Army Medical Services, in succession to the late Lieut.-General Sir William B. Leishman, K.C.B., K.C.M.G.

Major-General Fell served in France and Mesopotamia during the great war, and was eight times mentioned in dispatches. In 1918 he was lent to the Air Ministry, and acted as Director Medical Services R.A.F. till 1921. Subsequently he became Inspector Medical Services of the Army (1921-22), and Deputy Director Medical Services (1922-26), serving in Turkey, in the Northern Command, and in Egypt. He returned from Egypt to take up the appointment of Deputy Director-General Army Medical Services, in succession to Major-General Pollock, on June 1st, the day before Sir William Leishman died.

#### CHIEF MEDICAL ADVISER TO THE COLONIAL SECRETARY.

THE following circular letter has been addressed by the Secretary of State for the Colonies to officers administering the various colonies. It announces the appointment of a Chief Medical Adviser and defines his duties.

Downing Street,  
15th June, 1926.

Sir,

I have the honour to inform you that I have for some time had under consideration the question of the creation of a post at the Colonial Office of Chief Medical Adviser to the Secretary of State whose duties will be to advise me generally on all medical and sanitary matters arising in connection with the Colonies, etc. The need for such an appointment has become increasingly apparent in view of the importance of ensuring continuity of policy in medical administration and co-ordination of progressive action between different services.

2. The Lords Commissioners of the Treasury have sanctioned

the creation of this post for a period of three years in the first instance, with a salary at the rate of £1,500 per annum, and I have appointed Dr. A. T. Stanton, M.D., M.R.C.P., M.R.C.S., M.C.P. and S., D.T.M. and H., D.P.H., since 1921 Director of Government Laboratories in the Federated Malay States, to be my Chief Medical Adviser in the Colonial Office.

3. The duties attaching to this post are more particularly as follows:

(1) To advise the Secretary of State generally on all medical and sanitary matters in the Colonies and Protectorates, and for this purpose to have access to all necessary departmental documents.

(2) With a view to the improvement of sanitation in the Tropical Dependencies, to ensure, so far as is possible, continuity of policy, co-ordination of action between different administrations, and the introduction of new ideas in the work of the Colonial Medical Services.

(3) To maintain a personal liaison and co-operation with other Government departments and other bodies in relation to health work in the Colonies, and to keep in touch with the medical schools in the United Kingdom.

(4) To preside over the Colonial Advisory Medical and Sanitary Committee.

(5) To advise the Secretary of State on all questions relating to the personnel of the Colonial Medical Services.

(6) To assist in the interviewing candidates for appointment as Medical Officers in the Colonies, and to be a member of the sub-committee on Colonial Medical appointments.

(7) To advise on all changes in the regulations and conditions of the employment of Colonial Medical Officers.

4. To remove any possibility of misunderstanding I would point out that, as will be apparent from the foregoing summary of the duties of the Colonial Medical Adviser, the post will be solely of an advisory character with no executive functions, and will in no way affect the responsibility of the Governor and the Head of his Medical Department in regard to the administration of medical matters in each Colony.

5. The Colonial Medical Adviser will be accommodated at the Colonial Office, and a suggestion has been made that the Heads and senior members of the Colonial Medical Services should be encouraged to call upon him during their leave. Such a practice would, I think, have the advantage that it would establish close personal relations between the Colonial Medical Adviser and Colonial Medical Officers, and I have to request that the desirability of taking advantage of this suggestion may be brought to the notice of senior members of the Medical Department who are serving under your administration.

6. The actual date on which Dr. Stanton will take up his duties is not yet determined, but it is expected that he will be available for duty in August next.

I have the honour to be, Sir,

Your most obedient, humble servant,  
L. S. AMERY.

#### DEATHS IN THE SERVICES.

Colonel George Arthur Hughes, D.S.O., Army Medical Service (ret.), died on April 13th, aged 74. He was born at Clonmel, the son of the late James Hughes of Curragh Priwen, Rathormac, County Cork, and was educated at Trinity College, Dublin, where he graduated B.A., M.B., and M.S. in 1875. He entered the army as surgeon in 1889, became colonel on March 25th, 1904, and retired on August 26th, 1905. He served in Afghanistan in 1878-80 (medal); in the Boer War in 1899-1902 (34-85; in the Ashanti campaign of 1895-96 (Ashanti star); and in the Nile sent at the battle of Khartoum, was mentioned in dispatches, and received the medal, the Egyptian medal with a clasp, and the D.S.O.

The death of Lieut.-Colonel Reynolds Peyton Hetherington, R.A.M.C. (ret.), last November, aged 71, has only recently come to our notice. He was educated at Trinity College, Dublin, where he graduated M.A. in 1876, M.B. in 1878, and M.D. in 1897. He entered the army as surgeon in 1881, became lieutenant-colonel after twenty years' service, was placed on half-pay in 1907, and retired in 1909. He served in the Egyptian war of 1882 (medal with clasp); in the Nile campaign of 1884-85 (clasp); in Burma, with the Irrawaddy and North-Eastern columns, in 1891-92 (medal with clasp); and throughout the South African war, 1899 to 1902, in operations in Cape Colony and in the Orange Free State (Queen's and King's medals, with two clasps to each).

Brevet Colonel Henry Charlesworth, C.M.G., R.A.M.C. (ret.), died at Ealing on June 5th, aged 74. He was the son of the late Mr. M. Charlesworth of Longnor, Staffordshire, and was educated at Middlesex Hospital, taking the L.S.A. in 1872 and the M.R.C.S. in 1873. He entered the army as surgeon in 1875, became surgeon lieutenant-colonel after twenty years' service, and retired in October, 1902. He served in the Afghan war in 1878-80, and received the medal. He also accompanied, as medical officer, two special missions to the Sultan of Morocco in 1887 and in 1899-90. He received the C.M.G. in 1902, for services outside South Africa, in the South African war. After retirement he served as recruiting officer at Nottingham (1902) and in London (1909). He rejoined for service in the late war, and was employed on the north-east coast of England, and received the Order of St. John of Jerusalem for his services, as well as a brevet-colonelcy.

#### Obituary.

##### EDWARD HICKLING BRADFORD, M.D.,

Boston, Massachusetts.

THE death on May 7th of Dr. E. H. Bradford of Boston, Massachusetts, which we recorded in our issue of May 29th, removes a notable figure from the dwindling group of pioneers of modern orthopaedic surgery.

Edward Hickling Bradford was born in 1848, a direct descendant of a former governor of the State, and a member of that aristocracy of culture and service which has distinguished New England. He graduated at Harvard in 1869, in which university he was afterwards to become the first professor of orthopaedic surgery, in the chair endowed by the Buckminster Brown bequest. Having spent two years in Europe, he left general practice to take up orthopaedic surgery, which he studied under Taylor of New York. On returning to Boston he worked with Dr. Buckminster Brown, whom he afterwards succeeded as surgeon to the House of the Good Samaritan, the pioneer institution in Boston for the treatment of bone and joint disease in children. He became successively surgeon to out-patients at the City Hospital and surgeon to the Children's Hospital, until his work at the latter institution absorbed his attention. To this hospital he finally became surgeon-in-chief. His long connexion with it was concurrent with the gradual foundation and world-wide repute of the Boston school of orthopaedic surgery. Many visitors from Europe will associate his personality more than that of any one other surgeon with the work that was originated and performed there. His valuable work on the pathology and treatment of congenital dislocation of the hip-joint, both by bloodless and open methods, and his simple but valuable frame for the treatment of Pott's disease, are only specimens of the many improvements which he introduced into the practice of his specialty. One of the outstanding textbooks of orthopaedic surgery was produced by him in conjunction with the late Dr. R. W. Lovett, and *Bradford and Lovett's Orthopaedic Surgery* has been for years an authority, and has reached its fifth edition.

Personally Dr. Bradford was one of the most modest and unassuming of men. Despite physical afflictions—he lost an eye and was permanently disfigured by a bicycle accident, and in his old age became almost totally blind—he maintained an equable and cheerful outlook on life and learnt to read Braille in his old age. Speaking to a friend about his loss of sight he said: "I was tempted to take a despondent view of life, but soon, however, on reflection, I realized that all this was but incidental and superficial compared with the resources of life. I found that life was a very rich opportunity which I had only half explored. I found that life itself could be nothing more than a temporary aspect of that spiritual experience in which I might prepare myself for larger service. This reflection returned to me not only courage but enjoyment of life." His calm and confident belief was not destined to be interrupted by suffering or illness. He died of a sudden cerebral haemorrhage, probably before he could be aware of any disturbance, at the age of 78.

His influence on the Boston school will long continue, and his actions smell sweet and blossom in the dust.

Dr. ROBERT B. OSGOOD of Boston writes:

Professor Bradford was one of America's greatest surgeons and one of the most admirable of men. He will be remembered as a pioneer in the renaissance of orthopaedic surgery, as a public servant in many civic and military positions of responsibility, as a great teacher, and as former dean of the Harvard Medical School. His courage was as constant as his initiative was strong. Many institutions and undertakings owed their inception and development to his vision and guidance. Honoured by his university and his colleagues, beloved by students and patients, his spirit was yet most gentle and humble. He accepted great personal handicap in the loss of sight as a challenge to explore life more fully, and he found endless resources and great happiness. Rarely has a man left a more stimulating record or presented to the world an example more worthy of emulation.

Dr. ALEXANDER BUTLER died suddenly at his residence in Harrogate on June 12th. He was educated at the High School of Glasgow and graduated at Glasgow University. He commenced practice in Kilmacoll, but shortly afterwards moved to Port Glasgow, where he resided for nearly thirty years. Dr. Butler took an active part in the educational work of that town, being chairman of the educational committee. It was owing to his efforts that one of the merchant princes there erected a cottage hospital for the district. He also acted for over twenty years as surgeon to the Royal Garrison Artillery Corps. At the beginning of the Boer war he volunteered for service in South Africa, and was gazetted captain in the regular army. At the commencement of the great war he was a major in the Territorial Force, and very early went out to France. His work lay at various advanced stations, some of them within the firing line. Being invalided home with trench fever he afterwards acted officially at numerous home stations during the period of the war. He held the rank of colonel, and received the long service Territorial medal. Dr. Butler was an antiquary and anthropologist of no mean order, and had an extensive knowledge of Shakespeare combined with great literary ability. He was engaged in finishing a book on the antiquities of Fountains Abbey, which will be of great interest to the historian, and he had done much research work in the neighbourhood of Harrogate and Knaresborough. The world is the poorer for the loss of such men as Dr. Butler.

We regret to report the death of Dr. CLAUD ANTHONY HOLBURN of Darlington on the evening of June 16th. While reversing his car he capsized into a ditch and was killed outright. Dr. Holburn was only 40 years of age, and was just becoming well established in his practice, which he had started on leaving the R.A.M.C. after the war. He received his medical education at Sheffield, where he obtained the Kaye scholarship in 1904-05. He took the diplomas of M.R.C.S., L.R.C.P. Lond. in 1908. His former appointments included those of house-surgeon to the Sheffield Royal Hospital, assistant house-surgeon to the Chesterfield and North Derbyshire Hospital, and anaesthetist to the Hospital for Women and Children, Leeds. Dr. Holburn was a member of the Darlington Division of the British Medical Association. He leaves a widow and three young children.

Dr. LAURENCE McNABB of South Shields has died, after an illness of several months, at the age of 59. Dr. McNabb was a native of North Ireland, who received his medical education at the University of Durham, where he took the degree of M.D. After holding junior staff appointments at the Newcastle Infirmary and at Preston he served as medical officer to the Harton Institution, under the South Shields guardians. Dr. McNabb then entered private practice, and became district medical officer and public vaccination officer under the Poor Law authority. He was one of the managers of St. Bede's Roman Catholic School, South Shields. He took a keen interest in sport, and was one of the oldest members of the South Shields Golf Club. He leaves a widow, two sons, and five daughters.

Dr. HORATIO W. A. COWAN, who died on May 28th, was well known in London as a most energetic and thoroughly up-to-date practitioner. He was born in Inverness, and received his medical education at Aberdeen University, where he graduated M.B., C.M. in 1895. Afterwards he studied at St. Bartholomew's Hospital, and while acting as assistant to a practitioner also found time to hold clinical appointments at the Throat Hospital, Golden Square, Moorfields Eye Hospital, and the Brompton Hospital. He served for a time in the Royal Navy, passing out of Haslar first of his year. The want of professional work in the service made him retire after two years, to start in practice in Fitzroy Square, London, where he continued until his death. He was a most sympathetic practitioner, who never grudged time or work in the

interests of his patients. All who knew him soon recognized, beneath his quiet manner, the sterling character of the man and the solidity and soundness of his judgement in medical matters, founded on a deep and wide acquaintance with clinical medicine and medical literature. Dr. Cowan will be greatly missed by colleagues, patients, and his many friends. He was a most hard and industrious worker, often doing two or three men's work; especially during the war, when, in addition to being a voluntary medical officer to the Flying Corps, he acted as skin physician at Middlesex Hospital. These excessive demands on his strength probably undermined his resistance, and paved the way for the onset of the cardiac condition which was the cause of his sudden death. Outside his professional life Dr. Cowan had many interests; both motoring and yachting attracted him. He will indeed be missed by a large circle of friends and by many who have been under his care. He leaves a widow, one daughter, and a son, who is succeeding him in practice.

We regret to announce the death of Dr. SYDNEY GWENFFRWD MOSTYN, medical officer of health for Darlington, at the age of 59. He was killed in a motor accident on June 22nd while touring near Fort William in the Western Highlands. Dr. Mostyn received his medical education at Oxford and St. Bartholomew's Hospital, graduating M.B., Ch.B. in 1902; he obtained the M.R.C.S., L.R.C.P. diplomas in the same year, and the D.P.H. Camb. in 1903. In 1902 he became medical officer to the Infectious Diseases Hospital at Newcastle, and two years later received the appointment of medical officer of health for the county borough of South Shields. In 1911 he was appointed medical officer of health for Darlington, where he organized the first health week in that city two years later. Dr. Mostyn, who was a Fellow of the Society of Medical Officers of Health, the Physical Society of London, and the Royal Sanitary Institute, was very popular in Darlington, where he was an active member of the Rotary Club and the Darlington and Teesdale Naturalists' Field Club.

Dr. JOHN WILSON of Lanchester, county Durham, died on June 18th at the advanced age of 91. He was born in Scotland, and studied medicine at Glasgow University, where he graduated M.D. in 1860. After practising for a short time in his native country he became assistant to the late Dr. George Renton of Blackhill. He subsequently removed to Lanchester, where he was appointed medical officer under the Lanchester board of guardians, which post he resigned in 1914 after fifty-two years' service. In 1894 Dr. Wilson was appointed to the Commission of the Peace for the county; for many years he acted as chairman of the Lanchester bench. High tributes were paid to Dr. Wilson's work and character at the sitting of the Consett petty sessions on June 21st. He is survived by one daughter and four sons.

The following distinguished foreign medical practitioners have recently died: Dr. Brugnatelli, professor of obstetrics and gynaecology in the Sassari faculty of medicine; Dr. Aguilar Jordan, a well known paediatrist of Valencia; Dr. T. Wyder, formerly professor of gynaecology at Zürich; Dr. C. Ruggi, professor of gynaecology at Berlin; Professor F. von Soxhlet, the inventor of the well known apparatus for the sterilization of milk; Professor J. Kyrle, a Viennese dermatologist; Dr. S. Patellini Rosa, professor of social eugenics at Milan; and Dr. Edouard Moutard-Martin of Paris, a specialist in diseases of the chest.

THE LATE SIR HENRY MORRIS.—Mr. W. A. Maggs writes: In 1877, when I entered as a student at the Middlesex Hospital, Mr. Henry Morris (later Sir Henry) was the lecturer on anatomy. Both by his own personality and by his intimate acquaintance of the subject he was accustomed to keep the class well in hand, and thoroughly interested; indeed, he seemed to make the dry bones speak. His handsome presence, fine voice,

emphatic and lucid style, attracted his hearers, who soon became eager listeners, and, more important still, learners. If by chance one ever felt drowsy on these occasions it was not the fault of the lecturer, but due to a badly ventilated and overheated theatre, crowded with students. Anatomy lectures in those days were given at 4 o'clock, and followed immediately a large class held in the same theatre. His lectures on clinical surgery, delivered without a note, were really a delight as well as a profit, and I vividly recall, even at this distant period, some of them, and notably one on Caesarean section, in which he pleaded eloquently for its justification. His surgical operations, performed under a dense cloud of carbolic spray, were most carefully, skilfully, and deliberately executed, never hurriedly or with perturbation; and those involving a fine dissection—as, for example, a tumour in the anterior triangular space—showed him a master of his craft. His character and straightforward manner were an inspiration to his pupils, and all who had the privilege of coming under his influence, will hold him in respectful and grateful remembrance as a great surgeon, anatomist, teacher, and orator.

## Medical News.

THE University of London Bill was read a second time in the House of Lords on June 29th after a brief discussion, in the course of which the Archbishop of Canterbury expressed the hope that the position of the theological colleges would not be detrimentally affected. The bill is a Government measure, but is likely to be strenuously opposed in the House of Commons. The University of London Graduates' Association, of which Dr. Graham Little is president, has just issued two fly-leaves, calling upon graduates to bring pressure to bear upon M.P.s to procure the rejection of the measure. The chief grounds of objection seem to be the proposal to constitute a council to take on some of the functions of the present unwieldy Senate, and a fear that the interests of external students may be imperilled.

THE Minister of Health has issued a circular (698) to sanitary authorities and medical officers of health instructing them that it is not necessary for persons who have been in contact with a case of small-pox to abstain from their usual occupations, except when additional precautions are necessitated—as, for example, in the case of laundries or common lodging-houses, when the business or habits of the inmates of a house in which small-pox has occurred make it difficult for proper medical observation to be maintained. He finds that some local authorities when dealing with outbreaks of small-pox still think it necessary to quarantine in their homes the inmates of dwellings invaded by the disease, with the result that authorities are faced with claims for compensation for loss of wages. He therefore states that there is no legal authority for the payment of compensation in these circumstances, and it should not be expected that the Minister would be willing to sanction any such payment under the Local Authorities (Expenses) Act, 1887, in a case in which he was advised that the steps taken by the authority were not necessary for the protection of the public health.

THE KING has sanctioned the following promotions in and appointments to the Order of St. John of Jerusalem: As *Knights of Grace*, Captain C. A. Coventon, R.A.M.C.(T.A.), Dr. H. H. Bashford, Lieut.-Colonel J. C. Strathearn, M.D., F.R.C.S.Ed. As *Esquires*, Dr. Meredith Young, Dr. W. R. Bates, O.B.E., Major R. Briercliffe, O.B.E., M.B., Major J. A. Henderson, R.A.M.C.(T.A.), Dr. R. A. Clegg, Colonel J. J. Pratt, F.R.C.S., Major J. S. Mather, R.A.M.C.(T.A.).

THE eighty-fifth annual meeting of the Royal Medico-Psychological Association will be held at the house of the British Medical Association, Tavistock Square, on Tuesday, July 13th, and three following days. Lieut.-Colonel J. R. Lord, C.B.E., M.B., will be inducted as president in succession to the late Sir Frederick Mott, and on the afternoon of Tuesday (13th) will deliver his presidential address on the clinical study of mental disorders. On the morning of July 13th Dr. G. A. Auden will present a clinical study of the madness of Ajax as conceived by Sophocles. On Wednesday morning, July 14th, two papers will be read—one on encephalitis lethargica by Dr. R. L. Mackenzie Wallis, and the other by Dr. C. Farran Ridge on symptoms referable to the basal ganglia in dementia praecox and epidemic encephalitis. In the afternoon the association will meet at the London County Hall, when Dr. Shruball will read a paper on educational adaptation of the individual child, and the medical examination rooms, laboratories, and other departments will be visited. On Thursday morning, at the British Medical Association House, a discussion on psycho-analysis and its development will be opened by Dr. W. H. Potts, and in the afternoon the Maudsley Lecture, which is to be a preliminary

survey of the problem of the prevention of insanity, will be delivered by Professor George Robertson, President of the Royal College of Physicians of Edinburgh. After this Dr. F. H. Stewart will read a paper on Mendelism in bacteriology. In the evening the annual dinner will be held at the Victoria Hotel, for the commemoration of the charter. On Friday morning papers will be read on some forensic aspects of epilepsy by Dr. W. Norwood East, and on the prison psychosis by Dr. H. T. P. Young. In the afternoon a visit will be paid to the Horton Mental Hospital, Epsom, where demonstrations will be given by Colonel S. P. James, M.D., and Mr. P. G. Shuto, illustrating the infection of mosquitos and other points relating to laboratory work in connexion with the treatment of general paralysis by malaria. Afterwards Dr. Nicol, in charge of that department at the hospital, will give a clinical demonstration, and various departments of the institution will be visited.

THE St. Bartholomew's Hospital War Memorial will be unveiled by H.R.H. the Prince of Wales, President of the hospital, on Thursday, July 8th, at 3 o'clock.

THE extension of the dental school of Guy's Hospital will be opened on Thursday, July 8th, at 3 o'clock, by the Right Hon. F. Dyke Acland, Chairman of the Dental Board of the United Kingdom.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that Mr. Cairns Forsyth will give a clinical demonstration on Monday, July 5th, at 2.30 p.m., at the Royal Waterloo Hospital, and on Thursday, July 8th, at 3 p.m., Mr. MacCallan will give one in ophthalmology at the Royal Eye Hospital. Both demonstrations are open to the medical profession, without fee. Beginning on July 19th, a two weeks' vacation course will be held at the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham). The West End Hospital for Nervous Diseases will hold a late afternoon course from July 19th to August 11th in the out-patient department, at 73, Welbeck Street, W. There will be a series of demonstrations on eye diseases by members of the staff at the Royal Eye Hospital from July 12th to 24th, at 3 p.m. daily. Practical courses in obstetrics and child welfare are arranged to take place at the City of London Maternity Hospital; the duration of each course is one week. Practical courses in anaesthetics can be arranged at any time to suit post-graduates' requirements. Copies of all syllabuses, of the general course programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

A MEETING of the Society of Superintendents of Tuberculosis Institutions will be held at 122, Harley Street, W., on July 5th, at 3 p.m. Dr. S. Roodhouse Gloyne will open a discussion on unsolved pathological problems associated with tuberculosis, and Dr. F. R. G. Heaf will read a paper on sedimentation tests.

GENERAL medical practitioners are invited to the annual meeting of the Maternity and Child Welfare group of the Society of Medical Officers of Health, at Caxton Hall, Westminster, on July 6th, at 5.30 p.m.; they will also be welcomed at the subsequent dinner at the Florence Restaurant, Rupert Street, at 7.30 p.m., tickets for which may be obtained from Dr. Margaret Emslie, 1, Upper Montague Street, W.C.1.

FROM July 19th to 23rd a congress of chemists will be held in London, in association with the annual general meeting of the Society of Chemical Industry. A large number of other chemical societies are co-operating in the congress. Sir Frederic L. Nathan will give the presidential address on "Industrial efficiency and the elimination of waste," and Lord Balfour will deliver the Messel Memorial Lecture. Papers will be read on a large number of subjects; at a joint meeting of the Bio-Chemical Society and the London section of the Society of Chemical Industry, Dr. H. H. Dale will read a paper on "The experimental study and use of hormones," and Dr. J. W. Trevan a paper on "Biological assay of hormones." Many entertainments and excursions have been arranged. Inquiries about the congress should be sent to the General Secretary, Society of Chemical Industry, Central House, 46 and 47, Finsbury Square, E.C.2, from whom a preliminary programme of the meeting can be obtained.

THE Association of Special Libraries and Information Bureaux (General Secretary, Mr. G. W. Keeling, 38, Bloomsbury Square, W.C.1) was formed to make available, to all who wish to use it, scientific and other special information to be found in periodicals and libraries. With the assistance of the Carnegie United Kingdom Trust, the association is compiling a directory of sources of specialized information in Great Britain and Ireland. The British Medical Association is represented on the council of the new association by its intelligence officer, Miss A. L. Lawrence. Associate membership is open to anyone interested.

DR. W. W. KEEN calls our attention to the omission in our annotation on American medical libraries (BRITISH MEDICAL JOURNAL, May 22nd, p. 878) of any allusion to the library of the College of Physicians of Philadelphia, to which, however, we have made references on several previous occasions. This library now contains over 150,000 volumes. The report for the year 1925 shows that there has been considerable expansion. A number of interesting medical classics have been added, as well as many current medical publications. Dr. Keen has presented to the library a transcript and photostat-negative of a letter written by William Harvey, probably in 1631, to Viscount Dorchester; and proof copies of the portraits of Sir James Mackenzie and Sir Clifford Allbutt received from the editor of the BRITISH MEDICAL JOURNAL. The library committee recently sold the entire collection of duplicates in its possession to the medical school of the University of Otago, New Zealand, at a nominal price, for the formation of a library in that university.

DR. J. P. J. POWELL, on his retirement after thirty-five years of practice at Sennybridge, near Brecon, has been presented by his friends and patients with an illuminated address, a silver tea and coffee service, a cabinet of cutlery, and a cheque for over £300.

THE following have been elected Fellows of the Royal Sanitary Institute: Colonel Harold P. W. Barrow, C.M.G., D.S.O., O.B.E., late R.A.M.C., Dr. J. J. Buchan (M.O.H. Bradford), Miss Josephine L. D. Fairfield, C.B.E., M.D. (Divisional Medical Officer, Public Health Department, L.C.C.), Dr. James Fenton (M.O.H. Kensington), Dr. William Hanna (Deputy M.O.H. Liverpool), Dr. J. F. C. Haslam, M.G. (Tropical Diseases Bureau), Dr. J. J. Jervis (M.O.H. Leeds), Lieut.-Colonel G. R. Leighton, M.D. (Medical Officer (Foods), Scottish Board of Health), Dr. R. St. J. Macdonald (Department of Hygiene, McGill University, Montreal), Dr. A. T. Nankivell (M.O.H. Plymouth), Dr. H. P. Newsholme (M.O.H. Croydon), Dr. Harvey Sutton (Department of Public Instruction, Sydney, N.S.W.), Sir Edward N. Thornton (Union Health Department, Pretoria, S.A.), Sir Malcolm Watson (Klang, F.M.S.), Dr. J. B. Wilkinson (M.O.H. Oldham), and Dr. W. J. Wilson (Professor of Hygiene and Public Health, Queen's University, Belfast).

DR. F. E. FREMANTLE, M.P., has been appointed a deputy Lieutenant for the county of Hertford.

THE following appointments have recently been made in the Spanish medical faculties: Dr. Dámaso Rodrigo Pérez de Madrid, professor of children's diseases at Valencia; Dr. Fernando Casadésos y Castells, professor of oto-rhinolaryngology at Barcelona; Dr. Vidal Jordán, professor of children's diseases at Valladolid; Dr. Pedro Ara y Sarriá, professor of descriptive anatomy and embryology at Valencia; and Dr. Antonio García Tapia, professor of oto-rhino-laryngology in the Madrid Faculty of Medicine.

THE Carlo Forlanini Foundation has offered a prize for an original work on the morbid anatomy, pathology, or treatment of pulmonary tuberculosis, which must be sent in by December 31st, 1926. Further information can be obtained from the Director, Ospedale Maggiore, Milan.

THERE has recently been a considerable increase in the number of abortions in Germany. Thirty or forty years ago there were only nine or ten abortions in every hundred pregnancies, whereas at present the proportion is 40 per cent., and 89 per cent. of them are criminal. The birth rate has fallen from 36.9 to 21.6 per mille.

THE following subjects will be discussed at the section of medical electrology and radiology of the French Association for the Advancement of Science, to be held at Lyons from July 26th to 31st under the presidency of Professor Cluzet: (1) Radiodiagnosis of affections of the duodenum, introduced by MM. Bécère and Porcher of Paris; (2) Roentgenotherapy of epitheliomata, introduced by M. Coste of Lyons; (3) Electro-radiological treatment of neuralgia, introduced by MM. Zimmern and Cottenot of Paris; (4) Present technique of radium treatment of cancer, introduced by M. Réchov of Bordeaux; (5) Present technique of ultra-violet ray therapy. Further information can be obtained from Professor Cluzet, 106, Rue de l'Hôtel de Ville, Lyons.

PROFESSOR H. SELTER of Königsberg has succeeded Professor Kisskalt in the chair of hygiene at Bonn, and Professor Theodor Brugsch, director of the second medical clinic at Berlin, has succeeded Professor Jaksch in the chair of internal medicine in the German university at Prague. Professor Stoeckel of Leipzig has succeeded the late Professor Bumm in the chair of obstetrics and gynaecology at Berlin.

AMONG the subjects to be discussed at the Dermatological Section of the German Association of Natural Research, to be held at Düsseldorf from September 19th to 26th, are herpes zoster and varicella, introduced by Professor Lipschütz of Vienna, and malaria treatment of the early stages of syphilis, introduced by Dr. Benig of Essen.

PROFESSOR CHRISTIAN BAEUMLER, whose name stands eighth on the list of Fellows of the Royal College of Physicians of London, recently celebrated his ninetieth birthday at Freiburg in Baden, where he had become professor of medicine at the university and director of the medical clinic in the autumn of 1876; he retained these appointments until not very long ago. The reception took place in the aula of the university. The medical faculty of the university arranged a lunch in the town for Professor and Mrs. Baemler, and among those present were all the official personages of the university and town, many of the professor's former assistants, some of whom had specially come from abroad for the occasion, and a number of the medical practitioners of Freiburg and their wives. Professor Baemler was house-physician at the German Hospital in London from October, 1863, to 1866, and assistant physician from 1867 to 1872. He remembers his work in London with the greatest pleasure and has very often referred to his medical experiences there in conversation and in his lectures and published writings on a variety of medical subjects. At the German Hospital he contracted typhus fever and was the first to suggest the correct diagnosis of his illness; this fact was related long afterwards by the late Sir Hermann Weber, with whom he was on close terms of friendship. Sometimes the two made Alpine tours together in Switzerland and Tyrol, and both enjoyed to the uttermost the open-air exercise and beautiful scenery.

THE Council of the Medical Women's International Association will hold its next meeting in Prague on August 26th. Following this there will be meetings and social events to which any medical women will be welcome. The agenda of the open meeting includes discussions on (1) tuberculosis and pregnancy, (2) women police-surgeons. It is hoped that some members of the Medical Women's Federation of Great Britain will find it convenient to include Prague in their holiday itinerary. Any further particulars may be obtained from the secretary, Miss M. I. Robertson, M.B.E., 28, Weymouth Street, W.1.

FROM 1900 to 1925 inclusive 7,134 medical students, including 527 women, have been enrolled in the four Dutch universities of Leyden, Utrecht, Groningen, and Amsterdam. During the same period 4,201 students, including 239 women, became graduates.

THE date of the third International Congress for Life Saving and First Aid to the Injured, which is to be held at Amsterdam, has now been fixed for September 7th to 11th. The honorary president of the congress is Prince Henri of the Netherlands. The Duke of York is president of the British section of the congress. There are to be eleven sections, dealing with subjects appertaining to first aid in the emergencies of various activities in life. The St. John Ambulance Association and the National Fire Brigades Association are to send teams for international competitions in life saving and first aid. It is intended to form parties to travel from England to the congress, and reduced rates are offered. Dr. D. A. Coles, Professor E. L. Collis, Sir Thomas Oliver, and Dr. Theodore Thompson are the British members of the Permanent Committee. The secretary of the British section is Miss M. A. Harvey, 7, Cambridge Street, Hyde Park, W.2.

THE fifth congress of the International Union against Tuberculosis will be held at Washington from September 30th to October 2nd, when the principal subjects for discussion will be tuberculous infection in the adult, the anatomical structure of the tubercle, and the relation between milk and tuberculosis. The congress will be followed by the annual general meeting of the American Society for Combating Tuberculosis, to which members of the congress will be invited.

PROFESSOR R. CRUCHET, who has hitherto held the chair of general pathology and therapeutics, has been appointed professor of children's diseases in the Bordeaux Faculty of Medicine.

A CHAIR of otology has been founded at the Athens Faculty of Medicine, with Professor S. Oconomos as its first occupant.

*The World's Children* is the monthly journal of the Save the Children Fund, and is described also as the "English-speaking organ of the Declaration of Geneva." In the June number the Bishop of Gibraltar describes the work of the Anglo-Serb Children's Hospital in Belgrade, which is maintained by British charity through the Save the Children Fund. The hospital owes its origin to the energy of Dr. Katherine Macphail, who after the armistice devoted herself to the relief of sick and starving Serbian children; 40,000 children have been treated since the foundation of the hospital. The rest of this number of the journal consists in descriptions of the activities of various bodies on behalf of children throughout the world.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Atiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bucillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

### QUERIES AND ANSWERS.

**DR. D. M. MACDONALD** (Ariside, Westmorland) asks for references regarding the use of selenium in cancer of the lung.

#### THE ADMINISTRATION OF OXYGEN.

**DR. E. P. POULTON** (London, W.) writes in reply to "Oxygen," who asked for advice as to the best way of administering oxygen (*JOURNAL*, March 20th, p. 553): Haldane's apparatus, or a more satisfactory modification of it devised by Dr. Davies, and made by Siebe, Gorman and Co., Westminster Bridge Road, S.E., will certainly ensure the patient getting a sufficient concentration of oxygen, but this method is extremely wasteful. I am at present experimenting with a closed circuit form of apparatus in which any degree of concentration of oxygen may be administered, while there is no waste of oxygen at all. This apparatus is being made by Down Bros. In acute cases a moderately successful way of giving oxygen is a nasal catheter which is passed through to the back of the nose. It is certainly much the simplest method of giving it, as it requires no special apparatus, but it is impossible to obtain high percentage by this means.

#### CAUSE, PREVENTION, AND TREATMENT OF WHOOPING-COUGH.

**DR. P. F. JAMES** (Merthyr Tydfil) writes: The focus of infection in whooping-cough is probably the sublingual fossa, the virus irritating the sensory filaments of the glosso-pharyngeal nerve, causing contraction of the middle constrictor and stylo-pharyngeal muscles, constriction of the pharynx, irritation friction, prolonged paroxysmal coughs, whoops, and vomiting. The pulmonary gaseous diffusion is unbalanced; the blood is supersaturated with carbon dioxide and deficient in oxygen. The cyanosis produces paresis of the nerve centres in the medulla and elsewhere, relaxation of the constriction, and termination of the cough. Recumbency would account for the nocturnal frequency of the cough. A le junction of the frenum linguae of the mouth. Treatment should be the weak tincture of iodine (*B.I.*) lightly on alternate days with the children and the witness of ment. Treatment in institutions on these lines, with controls, would be desirable, and it is with a view to suggesting this that I am recording my personal experience.

\* \* The lesion to which Dr. James alludes has, of course, often been noted in describing the symptoms of whooping-cough. At one time, as pointed out by a correspondent in the **BRITISH MEDICAL JOURNAL**, March 8th, 1879 (p. 348), sublingual ulcer was looked upon as pathognomonic of the disease. The correspondent had found it so often absent in whooping-cough, and yet present in patients with severe cough, as in cases of catarrhal pneumonia, that he had come to the conclusion that ulcer of the frenum was caused by the tongue being projected over the lower incisor teeth—in fact, he regarded the ulcer as a complication of the disease from which the child was suffering. In a paper on whooping-cough by Drs. D. Paterson and J. M. Smellie (*BRITISH MEDICAL JOURNAL*, May 6th, 1922, p. 713) it is stated that sublingual ulcer was present in 18 per cent. of 62 cases in which it was looked for, and usually developed during the second or third week of the disease.

#### TUBERCULIN TREATMENT OF TUBERCULOSIS.

"**TUBERCULOSIS OFFICER**" writes: I note with interest the proposal of Dr. Camac Wilkinson to reopen his tuberculin dispensaries. May I ask if any investigation was made as to the treatment by the officers of the Ministry of Health, and, if so, what was the verdict as to the efficacy of the treatment?

\* \* Our correspondent probably has in mind the inquiry made in 1923 at the request of the Ministry of Health by the Medical Research Council. The matter was referred to at some length in our issue of December 8th, 1923 (p. 1107). It appears that three medical men were deputed by the Medical Research Council to visit Dr. Camac Wilkinson's dispensary, but did not have the advantage of meeting him. The report of the visitors was not, so far as we are aware, published and was described as confidential, but we were informed that, in their opinion, Dr. Camac Wilkinson's system of treatment "did not appear to have claims over other methods of treating tuberculosis, either with or without tuberculin, which would justify its general adoption." To this Dr. Wilkinson replied by the publication of an essay on the tuberculin dispensary for the poor. We did not then feel that the information in our possession was sufficient to justify the expression of a decided opinion. So far as we are aware, nothing further has happened since then until the publication of Dr. Wilkinson's book, recently reviewed (June 19th, p. 1039) in our columns. As the report was never published we do not know how thorough the visitation was, but we are inclined to think that in view of the increased interest now taken in treatment by tuberculin the time has come when the matter should be reopened. Letters on tuberculin in the treatment of tuberculosis will be found at page 35.

#### INCOME TAX.

##### Sale of Share in Practice.

"**NORTHERNER**" sold a half-share in his practice in January, 1925, and his partner paid him a sum down in October and another instalment in December, 1925. How should their returns be made for the year ending April, 1926?

\* \* A declaration should be made on the appropriate form, which the assessor or inspector will supply, setting out the average profits of the practice for the three years prior to April, 1925, and also the basis of division of the partnership profits. Then each partner should make a separate declaration setting out his share of the partnership profits, as shown in the other form, and any other income he may have. The payments made by one partner to the other for the purchase of the share in the practice are capital payments and do not affect their income tax returns.

##### Expense of Books.

**A. W. M.**, who holds an appointment in the navy, asks whether he understands correctly that there is an income tax allowance of £10 10s. for books and £7 7s. for medical publications.

\* \* There is no such standard allowance by law, the legal position being that a taxpayer is allowed against the assessment of the emoluments of employment expenses "wholly exclusively and necessarily in the performance of the duties of the office." It may be that there is a departmental rule to make the allowance quoted to persons holding such appointments as "A. W. M." holds, but we have no knowledge of it. If there is such a rule it would be convenient and not unreasonable. Anyhow, we advise our correspondent to claim that allowance when sending in his return.

##### Motor Car Replacement.

"**A. M.'s**" motor transactions have been as follows:

|                                      |       |
|--------------------------------------|-------|
| October, 1921—Purchased $\alpha$ for | £241  |
| March, 1925—Sold $\alpha$ for        | £25   |
| March, 1925—Purchased $\gamma$ for   | £284. |

The then cost of an  $\alpha$  car would have been £133. It will be seen from the above that "A. M." could have replaced his old  $\alpha$  by a new one at a net cost of £133—£25=£108; he actually expended £284—£25=£259, thereby obtaining a car that suited him better, but claimed that he should be allowed to treat as replacement expenditure that sum less the increased outlay (£284—£241=£43)—that is, £216.

\* \* "A. M." might refer to our reply to "J. A. S." in our issue of April 3rd last. The matter is one for the adjudication of the district commissioners, but there are strong arguments available to support the view that only £108 is allowable. We believe that the correspondent to whom we replied in April succeeded in obtaining from his inspector of taxes a larger allowance than was at first agreed to, and "A. M." may perhaps obtain some equitable compromise by discussion. We cannot recommend him to take his claim to the point of appealing personally to the Commissioners.

## Agents' Fees.

"McL." recently held a six months' assistantship. He has been assessed for those earnings, but the inspector refuses to allow a deduction for the fee charged by the agent through whom he took up the post.

\* \* If "McL." habitually takes up temporary assistantships we consider that he has grounds on which to claim that he is carrying on his profession in that way and is chargeable under Schedule D; in that event we think he has a good claim to the deduction on the ground that it is a normal and recurring expenso attributable to his earnings. If, however, he is assessable (as normally practitioners who act as assistants are assessable) for earnings of "employment," then the Schedule E rule applies and the inspector's view is correct—that is, that the expense was incurred not "in the performance of the duties" of the employment but anterior thereto, and, further, were not "necessary" so far as the terms of his contract of employment were concerned.

## Residence in the United Kingdom.

"X" left his employment in a hospital in England in July, 1923. During 1924-25 he was resident in England as his father's (non-paying) guest. In 1925-26 he was in England five months as his father's guest, spending the remaining seven months travelling with a patient. Can he be held to have been "domiciled" in England for 1925-26?

\* \* The material question is one of residence rather than domicile. "X" is liable to income tax as a British resident for 1925-26 unless he can show that when he came back to the United Kingdom he did so for a temporary purpose, and not with the intention of establishing a residence here. The question of intention is fundamental, and it is therefore impossible to answer the question specifically.

## LETTERS, NOTES, ETC.

## STERILIZING THE TYMPANUM.

"PUNCTILIOUS" writes: In your issue of June 12th there is a valuable and in some respects instructive contribution by Dr. Smurthwaite on "The treatment of throat and ear cases in children," which shows the magnificent results achieved by him in connexion with "the Gloucester scheme for the extension of medical services." The gratifying success attained is no doubt largely due to the fact that the work has been entrusted to the hands of a zealous and really expert specialist.

There is, however, at least one point in Dr. Smurthwaite's paper which, in my opinion, ought not to be allowed to pass unchallenged. In mentioning the well known technique usually carried out at the conclusion of the subradical mastoid operation in children he states that "the middle ear is made thoroughly aseptic" (the italics are mine) "by syringing through the aditus at the time of operation." It would be highly informing to be told exactly how Dr. Smurthwaite thinks this magical and immediate sterilization of the tympanum can be accomplished. I only know of two methods (neither often employed, I imagine) by which even some approach to sterilization can be brought about, and that is either (1) by thoroughly swabbing out the suppurating middle ear with some escharotic fluid, such as deliquescent pure carbolic acid or pure chromic acid, or else (2) by means of ionization. Syringing with the antiseptic solutions usually employed will obviously not make the middle ear aseptic right off the reel, as Dr. Smurthwaite would seem to infer, as surface lavage cannot reach the septic organisms embedded in the tissues.

I fancy the explanation of the appearance of the misstatement by Dr. Smurthwaite which I have quoted is to be found in the fact that he forgot to submit his original rough draft to careful revision. There is further internal evidence of this, for several inaccuracies have crept in, such as writing of "the drum" when the context shows that the drumhead (that is, the tympanic membrane) was in his mind; again, he writes as if the tonsillar sinus (or fossa) was the same thing as the bed of the tonsil; and yet again he implies that the reverse guillotine technique of Whillis and Pybus is the same as that of Sinder.

Although Dr. Smurthwaite's paper is unfortunately marred by these instances of careless writing and misleading statements, they do not affect the great value of the practical work he has so successfully carried out.

## SALT AND CANCER.

MR. FREDERICK T. MARWOOD, J.P., of Lancashire, a layman who has taken great interest in the causation of cancer, has sent us a reprint in pamphlet form of an article, "Salt and cancer," he contributed to the *Medical Officer* of January 9th last. Mr. Marwood is a modest person, who says that he is neither a Jenner nor a dairymaid; but that as jewels are sometimes found in dustbins, something of service might be found in the dustbin of his mentality. The article contains little except Mr. Marwood's view that salt is a powerful chemical, which has been recommended for removing ink stains and iron-mould and for cleaning baths, and that, therefore, in excess it may cause

serious trouble to our internal organs. This possibility Mr. Marwood supports by statistics showing the salt consumption in various countries compared with the incidence of cancer among the inhabitants. Cancer, it appears, is almost unknown among the Eskimos, while the death rate is very high in the United Kingdom, the United States, and other countries. Mr. Marwood probably appreciates the trickiness of statistics, but as the proceeds of his chief work, *What is the Root Cause of Cancer?* go to the British Empire Cancer Campaign, no doubt that body will see that due note is made of Mr. Marwood's evidence.

## HERBALISTS AND ACUTE APPENDICITIS.

DR. RICHARD E. M. TAUNTON (Hanwell, W.) writes: In an advertising booklet I have recently received from a firm of "herb specialists," of which many thousands are distributed annually, is an article on "Appendicitis or Inflammation of the Vermiform Appendix." It commences by stating that "in the olden days appendicitis was known as inflammation of the bowels and the deaths from this cause were few. People knew exactly what to do, especially those who were subject to the complaint." It then goes on to say that "the remedy is very simple and it is one which certainly should be tried in every case before an operation is consented to." The symptom of pain in the right iliac fossa is described, and the article then continues as follows: "On the first appearance of these pains the patient, if an adult, should take a dessertspoonful of olive oil. Two hours afterwards another dessertspoonful should be taken. This is often sufficient, but it will be more speedily effective if half an hour after taking the first dose of olive oil a wineglassful of an infusion of elder flowers and peppermint is taken. At the same time it would greatly ease the pain if hot fomentations were frequently applied to the part. If the disease is attacked by these means at the commencement the appendicitis has usually entirely disappeared after twelve hours. It will readily be admitted that this treatment if successful—and this is generally the case—is far preferable to a long and tedious period spent in recovering from an operation." Such advertising literature as this must have no small bearing on the mortality from appendicitis, especially in the many cases in which there is a normal pulse and temperature and the pain is only slight, and yet on opening the abdomen within a very few hours of the commencement of the pain an acutely inflamed and suppurative appendix is found. Furthermore, it dissuades the patient from seeking advice at an early stage of the disease.

## "SAFETY FIRST" IN PHOTOGRAPHY.

BURROUGHS WELLCOME AND Co. have issued a useful little book entitled *Safety First in Photography*. After a brief history of the development of photography there is a description of the Wellcome Photographic Exposure Calculator, remarks on rules for development with the aid of tabloid developers, and condensed tables of time and temperature for a number of well known developers. The use of tabloid desensitizers will, it is said, prevent the fogging of plates and films. After one minute's treatment in the dark in a solution of desensitizer, the plates or films can be developed by candle light. The book is illustrated with reproductions of photographs showing the effect of the use of tabloid products in developing, toning, and intensifying.

## THE ART OF ADVERTISING HEALTH.

ADVERTISEMENT is, of course, a fine art, and there is no reason why it should not be employed in the cause of health. The Wesleyan and General Assurance Society of Birmingham has a Health Service Bureau, which issues leaflets with a view to inducing its policy holders to prolong their lives. Three, which have been issued recently, are entitled "The care of the teeth," "Rheumatism," and "Whooping-cough." The first is adorned with a picture of a crocodile having its teeth cleaned by small birds, and the title, "The crocodile lives 200 years; if you wish to enjoy long life, keep your mouth clean." The second leaflet announces "3,000,000 weeks of work lost annually to the insured population through rheumatism." After such headings the plain statement, "Whooping-cough," seems almost an anticlimax. The advice contained in the leaflets seems sound, and the necessity for consulting the doctor and dentist is duly emphasized. As pathology and pessimism are eschewed, the leaflets should be useful if read by those for whom they are intended. It is stated that 660 medical officers of health and 120 education authorities use the leaflets for distribution.

## ERRATUM.

THERE is a regrettable printer's error in what is possibly the most important word in the notice of an appliance for bedridden patients with incontinence which has been devised by Messrs. W. B. Hilliard and Sons of Glasgow (*BRITISH MEDICAL JOURNAL*, June 19th, p. 1041). The word "piecer" in the sixth line should have been "piercer," which is descriptive of the principal novelty of the appliance—a rigid metal tube, which is made sharp-pointed so that it may easily pierce (perforate) a mattress.

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 46, 47, and 48 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears at page 53.

## Association Notices.

### NOTICE OF ANNUAL GENERAL MEETING.

#### NOTICE CONVENING MEETING.

NOTICE IS HEREBY GIVEN that the Annual General Meeting of the British Medical Association will be held in the Mechanics' Hall, Nottingham, on Tuesday, July 20th, 1926, at 2 p.m. Business: (1) Minutes of last Meeting; (2) Appointment of Auditors; (3) Report of election of President for 1927-28.

ALFRED COX, L. FERRIS-SCOTT,  
Medical Secretary. Financial Secretary and  
Business Manager.

### NOTICE OF EXTRAORDINARY GENERAL MEETINGS.

NOTICE IS HEREBY GIVEN by Order of the Council that an Extraordinary General Meeting of the British Medical Association will be held in the Mechanics' Hall, in the City of Nottingham, on Friday, the 16th July, 1926, at 4.45 o'clock in the afternoon, when the following Resolution will be proposed as an Extraordinary Resolution, namely:

That the Articles of Association of the British Medical Association be altered in manner following, namely:

- (1) By adding to paragraph (a) of Article 10 the following proviso, namely:

"Provided that no such representation shall be entertained if made by a Division or Branch within an area outside the United Kingdom for which a Federal Council has been formed under the Articles and By-laws where that Federal Council has been invested with the powers of paragraph (c) of this Article."

- (2) By deleting the whole of paragraph (b) of Article 10 and inserting in place and stead thereof the two following new paragraphs, namely:

"(b) The Council shall have power, on the application of the Branches within an area outside the United Kingdom for which a Federal Council has been or is being formed under the Articles and By-laws, to invest that Federal Council with the powers of the next succeeding paragraph of this Article."

"(c) (i) The Council of each Branch not in the United Kingdom, having a membership of not less than thirty and not being within the area of a Federal Council invested with the powers of this paragraph, upon the representation of any two members of such Branch, and

"(ii) Any Federal Council invested with the powers of this paragraph, upon the representation of any Branch within the area of that Council,

shall have power at a Special Meeting of the Branch Council or Federal Council (as the case may be), convened at not less than one month's notice, and after due inquiry of which not less than twenty-eight days' notice in writing, specifying the time and place at which he may be heard in his defence, shall have been given to the Member, to expel from membership of the Association any member of such Branch whose conduct shall be held by the Branch Council or the Federal Council (as the case may be) to be such as to render him liable to expulsion under paragraph (d) of the last preceding Article."

- (3) By inserting in original paragraph (c) of Article 10 immediately after the words "Branch Council" the words "or of a Federal Council."

- (4) By inserting in original paragraph (e) of Article 10 immediately after the words "Branch Council" the words "or by a Federal Council."

- (5) By relettering original paragraphs (c), (d), and (e) of Article 10, (d), (e), and (f) respectively.

Should the above Resolution be passed by the requisite majority it will be submitted for confirmation as a Special Resolution to a further Extraordinary General Meeting, and such meeting will be held at the British Medical Association House, Tavistock Square, London, W.C.1, on Tuesday, the 3rd day of August, 1926, at 2.30 o'clock in the afternoon, for the purpose of considering and, if thought fit, confirming such Resolution as a Special Resolution accordingly.

Dated this 21st day of June, 1926.

By Order of the Council,

L. FERRIS-SCOTT,  
Financial Secretary and  
Business Manager.

British Medical Association House,  
Tavistock Square, London, W.C.1.

### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: COVENTRY DIVISION.**—A special meeting of the Coventry Division will be held at the Coventry and Warwickshire Hospital on Tuesday, July 6th, at 8.30 p.m. Agenda: Correspondence; instructions to representatives.

**CAMBRIDGE AND HUNTINGDON BRANCH.**—The eighty-second annual meeting of the Cambridge and Huntingdon Branch will be held at the Icknield Hall, Letchworth, Herts, on Thursday, July 8th, at 1 p.m. Agenda: Annual report and election of officers. At 1.30 members will be entertained at lunch by the President-Elect, Dr. Hyslop Thomson, and the Chairman of the East Herts Division, Dr. Norman Macfadyen. After lunch Dr. Hyslop Thomson will deliver his presidential address on the diagnosis of disease in relation to preventive medicine.

**CAPE OF GOOD HOPE (WESTERN) BRANCH.**—A meeting of the Cape of Good Hope (Western) Branch will be held on Friday, July 30th, when Professor M. R. Drennan and Professor W. A. Jolly will introduce a discussion on the heart.

**EAST YORK AND NORTH LINCOLN BRANCH.**—The seventieth annual meeting of the East York and North Lincoln Branch will be held in Powolny's Banqueting Rooms, King Edward Street, Hull, on Saturday, July 10th, at 1 p.m. Luncheon at 1.30, at which Dr. D. R. Moir will take the chair and deliver his inaugural address.

**LANCASHIRE AND CHESHIRE BRANCH: LIVERPOOL DIVISION.**—A meeting of the Liverpool Division will be held at the Liverpool Medical Institution on Wednesday, July 7th, at 4 p.m. Agenda: Instructions to representatives to Annual Meeting; an appeal by Dr. R. W. MacKenna for greater support to medical charities.

**NORFOLK BRANCH.**—The annual meeting of the Norfolk Branch will be held at the Norfolk and Norwich Hospital on Wednesday, July 7th, at 3.30 p.m. Agenda: Report of Branch Council and annual statement; induction of the new President, Mr. William Henry Fisher, M.S., M.B., B.Ch., by the retiring President; appointment of a President-Elect and two Vice-Presidents. Address by Mr. Aleck William Bourne, M.B., B.Ch., Cantab., F.R.C.S., obstetric surgeon, St. Mary's Hospital and Queen Charlotte's Hospital, on the scope of Caesarean section. Tea will be served in the hospital grounds, by the kind invitation of Dr. and Miss Fisher, at 4.15.

**OXFORD AND READING BRANCH.**—The annual meeting of the Oxford and Reading Branch will be held at the Royal Berkshire Hospital, Reading, on Friday, July 9th, at 3.15 p.m. Agenda: Election of officers. Discussion on exophthalmic goitre: (a) Surgical treatment, Mr. Romanis; (b) Medical aspects, Dr. Gardiner-Hill; (c) Cardiac complications, Dr. Cassidy. Cases will be shown by Sir Stewart Abram, Mr. Secretan, Dr. Esther Carling, and Dr. Lambert. In the forenoon the Collier Golf Cup will be competed for at Huntercombe against bogey. Members may choose their partners, but must play at three-quarters of lowest handicap. Cards to be handed to the secretary before the clinical meeting.

**SOUTHERN BRANCH: WINCHESTER DIVISION.**—A meeting of the Winchester Division will be held at the George Hotel, Winchester, on Wednesday, July 7th, at 3 p.m. The business includes instructions to the divisional representative. At 3.30 a British Medical Association Lecture on the diagnosis and treatment of placenta praevia will be given by Dr. J. D. Barris, F.R.C.P., F.R.C.S., physician accoucheur, St. Bartholomew's Hospital. A large attendance is hoped for; non-members will be very welcome.

**YORKSHIRE BRANCH: SHEFFIELD DIVISION.**—A general meeting of the Sheffield Division will be held at the Church House, St. James's Street, Sheffield, on Friday, July 9th, at 8.30 p.m. It is especially desired that all members will endeavour to attend. Agenda: Annual Report of Council, which will be presented as follows: *Science*, Dr. Barnes; *Medical Ethics*, Dr. Russell; *Medico-Political*, Dr. Forbes; *National Insurance*, Dr. Helm; *Puerperal Morbidity and Mortality*, Mr. King.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

SURGEON REAR-ADMIRAL A. MACLEIN, C.B., D.S.O., is placed on the retired list at own request, in order to facilitate the promotion of more junior officers.

Surgeon Commander P. F. Alderson is placed on the retired list with the rank of Surgeon Captain.

Surgeon Commanders J. McA. Holmes, D.S.O., to the *Pembroke* for R.N. Hospital, Chatham, temporary additional; A. R. Schofield to the *Iron Duke* and as Squadron Medical Officer on recommissioning; J. G. Boal to the *Victory* for R.N. Hospital, Haslar.

Surgeon Lieutenant Commanders A. C. Shaw to the *Pembroke* for R.N. Hospital, Chatham; A. G. Bee to the *Frida*, additional for R.M. Infirmary, Plymouth; A. W. North to the *Ambrose*.

Surgeon Lieutenant C. H. Savory to be Surgeon Lieutenant Commander.

Surgeon Lieutenants R. R. Baker to the *Iron Duke* on recommissioning; J. H. B. Crosbie to the *Agamemnon* (July 14th) and to *Criticism* (undated).

Surgeon Lieutenant (short service) D. H. Kernohan has transferred to the permanent list.

Dr. W. T. Donovan has entered as Surgeon Lieutenant and appointed to R.N. Hospital, Haslar, for course.

### ROYAL NAVAL VOLUNTEER RESERVE.

Probationary Surgeon Lieutenants L. D. Nelson and D. R. Burbury to R.N. Hospital, Haslar, for twenty-eight and fourteen days' training respectively.

### ROYAL ARMY MEDICAL CORPS.

Colonel F. F. Carroll, D.S.O., half-pay list, and Colonel N. H. Rees, late R.A.M.C., retire on retired pay.

Captain W. Bruce, O.B.E., relinquishes the acting rank of Major.

R. L. J. Le Clezio to be temporary Lieutenant.

## ROYAL AIR FORCE MEDICAL SERVICE.

Flight Lieutenant A. E. Barr-Sim is promoted to the rank of Squadron Leader.

Flight Lieutenants (Honorary Squadron Leader) C. A. Meaden to No. 29 Squadron, Duxford; R. L. C. Fisher to No. 32 Squadron, Kenley.

Flying Officer H. W. Corner is promoted to the rank of Flight Lieutenant.

Flying Officers E. J. Jenkins to Station Headquarters, Birmham Newton; M. J. Marren to No. 3 Squadron, Upavon; S. F. Heatley to School of Technical Training (Men), Manston; P. H. Perkins to R.A.F. Depot, Uxbridge.

## REGULAR ARMY RESERVE OF OFFICERS.

## ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel H. M. Nicholls, having attained the age limit of liability to recall, ceases to belong to the Reserve of Officers.

## INDIAN MEDICAL SERVICE.

Colonel Francis H. G. Hutchinson, C.I.E., to be Major-General, vice Major-General Thomas Henry Symons, C.S.I., O.B.E.

Lieut.-Colonel C. B. McConaghy, an Agency Surgeon, on return from leave, is posted as Legation Surgeon, Nepal, and ex officio Assistant to the British Envoy at the Court of Nepal.

Captains to be Majors: William Peat Hogg, M.O., V. R. Mirajkar, M. M. Khan.

Captain T. A. Doran is appointed to officiate as Executive Officer, Kikee Cantonment, in addition to his ordinary duties, vice Captain F. R. Bailey, granted privilege leave.

## SUPPLEMENTARY RESERVE OF OFFICERS.

## ROYAL ARMY MEDICAL CORPS.

Captain S. P. Wilson, from General List, T.A., Manchester University Contingent, Sen. Div. O.T.C., to be Lieutenant.

Lieutenants to be Captains: W. G. Burns and A. R. Balmain.

## VACANCIES.

BEDFORD COUNTY HOSPITAL.—Assistant House-Surgeon (unmarried). Salary £130 per annum.

BOURNEMOUTH: ROYAL VICTORIA AND WEST HANTS HOSPITAL.—House-Surgeon (male, unmarried). Salary at the rate of £120 per annum.

BRIGHTON: ROYAL SUSSEX COUNTY HOSPITAL.—House-Surgeon (male). Salary £150 per annum.

BRISTOL: CITY AND COUNTY OF BRISTOL.—Assistant Tuberculosis Officer. Salary £600 per annum.

BRISTOL ROYAL INFIRMARY.—Surgical Registrar.

CAPE TOWN: DIVISIONAL COUNCIL OF THE CAPE.—Medical Officer of Health (male). Salary £1,100 for first year, rising to £1,200 for the third year.

ESSEX COUNTY HOSPITAL, Colchester.—Assistant House-Surgeon (male). Salary £150 per annum.

HALFAX: ROYAL HALFAX INFIRMARY.—First House-Surgeon (male, unmarried). Salary £250 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.3.—(1) Resident Medical Officer; salary £500 per annum. (2) House-Physicians; honorarium £50 per six months.

GLoucestershire ROYAL INFIRMARY.—Two Junior House-Surgeons. Salary £150 per annum.

IPSWICH: COUNTY BOROUGH OF IPSWICH.—Assistant Medical Officer of Health and Assistant School Medical Officer (woman). Salary £600 per annum.

KING EDWARD VII WELSH NATIONAL MEMORIAL ASSOCIATION.—Assistant Resident Medical Officer at the South Wales Sanatorium, Talgarth. Salary £200 per annum.

LONDON HOSPITAL, E.1.—Gynaecological Surgeon.

LONDON LOCK HOSPITAL, Harrow Road, W.9.—House-Surgeon at the Female Lock Hospital. Salary at the rate of £150 per annum.

METROPOLITAN ASYLUMS BOARD.—Medical Superintendent in the Infectious Hospitals Service. Salary £300 per annum.

MILDMAY MISSION HOSPITAL, Austin Street, E.1.—Honorary Emergency Surgeon.

OXFORD: WINGFIELD ORTHOPAEDIC HOSPITAL, Headington.—House-Surgeon (male). Salary at the rate of £100 or £150 per annum, according to experience.

ROCHESTER: St. BARTHOLOMEW'S HOSPITAL.—Honorary Pathologist.

ROTTERHAM HOSPITAL.—Junior House-Surgeon (male). Salary £150 per annum.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Ventnor.—Junior Medical Officer (male). Salary at the rate of £300 per annum.

SCARSDOUGH HOSPITAL AND DISPENSARY.—Two House-Surgeons. Salary at the rate of £125 per annum.

SHREWSBURY DISPENSARY.—Vacancy on the Medical Staff.

STOCKPORT INFIRMARY.—Resident House-Physician. Salary £175 per annum.

VICTORIA HOSPITAL FOR CHILDREN, Tite Street, S.W.3.—(1) House-Physician. Salary at the rate of £100 per annum each.

AND LEYTON CHILDREN'S AND GENERAL HOSPITAL.—(male). Salary £100 per annum.

Hammersmith Road, W.6.—Resident Assistant per annum.

WILLESDEN GENERAL HOSPITAL, Harlesden Road, N.W.10.—Casualty Officer (non-resident).

*This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.*

## APPOINTMENTS.

GAWNE, E. S., M.R.C.S., L.R.C.P.Lond., D.P.H., D.M.R.E.Liverp., Medical Superintendent, Townley's Hospital, Bolton.

ROBINSON, James S., M.B., B.Ch.Dub., F.R.C.S.Edin., Honorary Surgeon and Orthopaedic Surgeon, Cheltenham General and Eye Hospital.

CHRISTIE CROSS HOSPITAL.—House-Surgeon: R. A. Fitzsimons, B.Sc.Lond., M.R.C.S., L.R.C.P. House-Physician: J. Powell Evans, M.R.C.S., L.R.C.P.

CRYSTING FACTORY for the Rothsay for the Wirelicor R. Ch.B.Glas., D.P.H.Camb., Agertwood, M.B., Ch.B.Vict.,

## DIARY OF SOCIETIES AND LECTURES.

VICTOR HORSLEY-MEMORIAL LECTURE by Mr. Wilfred Trotter, M.S., F.R.C.S.: The Insulation of the Nervous System. British Medical Association House, Tavistock Square, W.C.1, Fri., 5 p.m.

## POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—*Special Demonstrations.* At Royal Waterloo Hospital in Clinical Surgery: Mon., 2.30 p.m. At Royal Eye Hospital, Southwark: Thurs., 5 p.m. *Hospital for Diseases of the Skin*, Blackfriars, S.E.: Afternoon Course in Dermatology, Tues., 2.30.

CANCER HOSPITAL, Fulham Road, S.W.3.—Fri., 4.30 p.m., Cachexia of Malignant Disease and its Treatment.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, W.C.—Fri., 3 p.m., Indications for the Radical Mastoid Operation.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, 5.—Mon., 10 a.m., Surgical; 10.30 a.m., Gynaeco- and Ear Operations; 2 p.m., Medical, Surgical, Operations; 6.30 p.m., Venereal Department.

Surgical, Throat, Nose, and Ear Clinics, Operations; 3 p.m., Demonstration of Illustrative Cases of Mental Disease at the Colney Hatch Mental Hospital, New Southgate, N.11. Wed., 10.30 a.m., Operations; 2 p.m., Medical and Eye Clinics; 3 p.m., Pathological Demonstration of Tumours of the Breast; 5.30 p.m., Venereal Department. Thurs., 10.30 a.m., Dental; 2 p.m., Medical, Surgical, and Throat, Nose, and Ear Clinics, Operations (Surgical and Gynaecological). Fri., 10.30 a.m., Eye Operations; 2 p.m., Surgical, Medical, and Children's Clinics, Operations; 6.30 p.m., Venereal.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Western Infirmary: Tues. and Thurs., 3 p.m., Clinical Gynaecology; Mon., 9.15 a.m., and Tues., 2.30 p.m., Dermatology. At Royal Hospital for Sick Children: Daily (except Sat.), Medical Diseases of Children.

## British Medical Association.

OFFICES, BRITISH MEDICAL ASSOCIATION HOUSE,  
TAVISTOCK SQUARE, W.C.1.

## Departments.

SUBSCRIPTIONS AND ADVERTISEMENTS (Financial Secretary and Business Manager, Telegrams: "Medical Secy B.M.A. London").

MEDICAL SECRETARY: Tel. 11, Westcent, London.

Telephone numbers of British Medical Association and British Medical Journal, Museum 9861, 9862, 9863, and 9864 (internal exchange, four lines).

SCOTTISH MEDICAL SECRETARY: 6, Drumsheugh Gardens, Edinburgh. (Telegrams: Associate, Edinburgh. Tel.: 4561 Central.)

IRISH MEDICAL SECRETARY: 16, South Frederick Street, Dublin. (Telegrams: Bacillus, Dublin. Tel.: 4737 Dublin.)

## Diary of the Association.

JULY.

6 Tues. City Division: Metropolitan Hospital, 9.30 p.m.

Coventry Division: Coventry and Warwickshire Hospital, 8.30 p.m.

7 Wed. Liverpool Division: Liverpool Medical Institution, 4 p.m.

Norfolk Branch: Annual Meeting, Norfolk and Norwich Hospital Mr. A. W. Bourne on the Scope of Caserecord Section, 3.30 p.m.

Winchester Division: George Hotel, 3 p.m. B.M.A. Lecture by Dr. J. D. Barris on the Diagnosis and Treatment of Placenta Praevia, 3.30 p.m.

8 Thurs. Cambridge and Huntingdon Branch: Annual Meeting, 1 p.m. Lunch, 1.30.

9 Fri. Oxford and Reading Branch: Annual Meeting, Royal Berkshire Hospital; Reading: Discussion on Exophthalmic Goitre, 3.15 p.m. Branch Council, 2.45.

Sheffield Division: Church House, St. James's Street, 8.30 p.m.

10 Sat. East York and North Lincoln Branch: Annual Meeting, Powolny's Banqueting Rooms, Hull; 1 p.m.; luncheon, 1.30.

16 Fri. Annual Representative Meeting, Nottingham, 10 a.m.

17 Sat. A.R.M.

19 Mon. Council Meeting (Nottingham).

20 Tues. A.R.M. Annual General Meeting.

21 Wed. Council Meeting.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcement of Births, Marriages, and Deaths is 2s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.*

## BIRTHS.

GARRATT.—On June 26th, at Myrtle House, Dunstable Road, Luton, 10 Winefree Mary, wife of Frank Garratt, M.R.C.S., L.R.C.P., a son.

MONON.—At St. Winifred's, Church Street, Edmonton, N.9, on June 19th, 1926, the wife of M. P. Kesava Menon, M.B., a son—Asoka.

POSTON.—On June 27th, at Mrs. McCubbin's Nursing Home, Withington, Manchester, to Margaret (née Macmillan), M.B., the wife of Richard I. Poston, M.D.; Thorncliffe, Fallowfield, Manchester, a son.

## MARRIAGE.

PANTON.—HEATH.—On June 24th, at St. Mary's ( ), by the Rev. R. Main, assisted by the Rev. J. D. Barris, M.D., Ch.M., F.R.C.S.Eng. and Edin., Dr. J. E. Panton, and Mrs. W. A. Bridson of Bolton, to Kathleen Ann, only daughter of Mr. and Mrs. Robert Heath, of Vernon Lodge, Brooklands, Cheshire.

## DEATHS.

CROWTHER.—On June 11th, at his residence, Marloes, Russell Road, Lee-on-Solent, John Woodward Crowther, M.R.C.S., L.S.A.

MACLAY.—At Bamburgh, suddenly, on June 26th, Neil MacLay, M.B., Ch.M., of 2, Fenham Terrace, Newcastle-on-Tyne, aged 53 years, dearly beloved husband of Mary MacLay.

## A British Medical Association Lecture ON ANGINA MINOR.

DELIVERED AT HASTINGS, JUNE 1ST, 1926,

BY

JOHN HAY, D.L., M.D., F.R.C.P. LOND.,

PROFESSOR OF MEDICINE, LIVERPOOL UNIVERSITY; SENIOR PHYSICIAN  
AND PHYSICIAN IN CHARGE OF HEART DEPARTMENT, LIVERPOOL  
ROYAL INFIRMARY.

ANGINA MINOR is a condition of some practical importance, and I trust that its consideration will help to crystallize our ideas; for there is still, in spite of much writing and talking, a certain haziness as to the significance of some of the pains and discomforts located in the precordial and subternal regions.

Up to December 31st, 1925, I have careful notes of 472 patients suffering from angina (309 up to July 31st, 1925, and 163 to December, 1925), mostly private patients; and it is on a careful scrutiny of these records that I base my remarks.\*

One outstanding feature of the study of medicine to-day is the much greater attention paid to symptoms than to the physical signs of disease. In the latter part of the nineteenth century it was the physical signs of heart disease which occupied the minds of the profession, and the aim was to correlate the physical signs with the gross present. This attitude dominated

Now with the swing of the pendulum the cross-examination of a patient is often considered even more important than the physical examination, and both are made with the object of obtaining a clear conception of the functioning power of the organ at fault, whether that organ be the heart, the kidneys, the pancreas, the liver, or any other viscus. For an organ may be gravely inadequate and yet present few, if any, objective signs of disease. It is here, in the assessing of the functioning power of the kidneys and pancreas, to give but two instances, that biochemistry has come into its own.

### EARLY SYMPTOMS.

Symptoms are the earliest manifestations of disease more often than physical signs. There is some subjective deviation from the normal, such as discomfort, pain, exhaustion, or lassitude. The elucidation of the meaning of such deviations from the normal and their prognostic significance was the aim underlying all the work of the late Sir James Mackenzie. He, more than any other man, focused the attention of the world of medicine on the subjective aspect of disease. Of all subjective sensations pain is the most arresting, and is of the nature of a protective reflex. We are saved from destruction by the pain which we deplore. This is true even if we may have to admit that on occasions the anguish proves too great for the human mechanism, and becomes, in fact, the lethal factor precipitating the end which it is its function to avert. Peculiarly is this the case in patients suffering from angina pectoris, and it is essential that we should be familiar with the earliest manifestations of this condition or symptom complex, in order that our patients may have the benefit of a correct and early diagnosis, so that their lives may be ordered aright and their days lengthened.

"By angina pectoris I have in mind an arresting form of cardiac pain, subternal rather than submammary, in which the patient is conscious of a sense of oppression, or constriction, which may reach a high grade of intensity, even a condition of intolerable anguish. This pain has certain well recognized lines of radiation and is often induced by effort or emotion. There are in addition characteristic associated symptoms not invariably present—notably the sense of impending death, and indescribable anguish of mind accompanied by varying vasomotor disorders, such as cold sweats and deathly pallor." (Bradshaw Lecture, BRITISH MEDICAL JOURNAL, November 24th, 1923.)

With few exceptions, the full-blown stark anginal seizure cannot fail of recognition. It is otherwise with the earlier manifestations when such are present, and it is these less

obtrusive indications which I wish to discuss—symptoms which are often not recognized as anginal in nature, and in consequence their ominous significance is overlooked.

In 1905 Sir James Goodhart, in the Cavendish Lecture, said, "Angina is common among us if we are on the look-out for the milder forms," and with this opinion I entirely agree. Angina minor has been labelled the "petit mal" of angina, and Sir James Goodhart referred to it as "larval." Both terms indicate that there is an essential relationship between the mild and the grave forms. It is merely a question of degree, for both are true angina.

Minor angina has also been called "fractional," because the patient may only manifest "one, or at any rate only a fraction, of the essential characteristics of the major anginas; that is, it may lack some of those characteristics always associated in our minds, and in those of the general public, with angina."

Minor angina may be, and often is, a premonitory symptom, but one full of significance to the understanding clinician. Most patients who suffer from major angina will, when carefully questioned, give a history indicating that for some years previous to the first major attack there were larval or minor manifestations, anginal in nature.

Again, both major and minor may alternate irregularly in the same patient, or the minor may come as an after-math or echo of a previous major attack. In such a case, the diagnosis being then beyond question, an opportunity is given of studying the more elusive symptomatology of the milder disease fortified by the knowledge of its real significance.

### CAUSE AND CHARACTER OF THE SYMPTOMS.

In angina minor, as in angina major, the symptoms result from cardio-vascular inadequacy, for the heart is in difficulties. Of these symptoms the commonest is subternal discomfort or pain on exertion or exposure to cold. This varies in degree and also in character. It is described by the patient as "a sense of oppression," "tightness," "constriction," a "feeling of weight," sometimes merely as "emptiness."

The site of the sensation is subternal, often in the middle or upper third, but it may be most marked at the lower third of the sternum, and sometimes even in the epigastrium, in "the pit of the stomach." This peculiar feeling is most commonly referred to by the patient as "indigestion," and not seldom he has been treated as a "dyspeptic" for years before the nature of the discomfort is revealed by an attack of angina major. These patients not uncommonly develop the habit of air swallowing, and an attack of angina minor simulating indigestion is accompanied by repeated attempts to "bring up the wind." When a sufficiency has been swallowed it is belched up, with undoubted relief to the patient. Such a sequence confirms the patient, and at times even his doctor, in the view that flatulence is the correct interpretation of the symptoms. And this view is still further corroborated by the fact that any exercise following immediately upon a meal—more particularly breakfast—is extremely likely to precipitate an attack.

The pains of angina, major or minor, are neither stabbing nor intermittent; they are continuous and persistent and have a crescendo and diminuendo quality, increasing in intensity if the effort which induced them is continued, and tending to cease when the patient rests.

The statement that anginal pain is an indication of myocardial exhaustion or evidence of myocardial failure seems to me to require modification, for cardiac failure may advance to an extreme degree without anginal pain, and definite anginal pain will sometimes disappear as cardiac failure becomes more pronounced.

The first manifestation of cardiac inadequacy may be pain, followed by dyspnoea if the effort is continued; yet at a later date in the same patient dyspnoea is the earliest sign of cardiac embarrassment, pain only manifesting itself if the patient persists in the effort. This may, of course, be due partly to variations in the threshold of pain, but I do not believe that that is the full explanation.

\* I gladly acknowledge the great courtesy of the medical men in charge of these patients, a courtesy which has enabled me to keep in touch with the after-histories.

The causes which induce anginal pain have this characteristic—they are such as to bring about a rapid strain on the arterial side of the circulation and especially on the left ventricle. The two common exciting factors are effort and exposure to cold. In a large proportion of anginal patients there is either a lesion of the coronary arteries or persistent hyperpnoea; in the first, the supply of blood to the myocardium ceases to be adequate when the heart is called upon for an increased output; in the second, the left ventricle and the aorta are carrying the heavy load of a raised blood pressure.

Effort and exposure to cold, and at times excitement, result in a sudden strain, and the response to this strain is manifested in terms of pain. After a short rest and a more gradual resumption of the effort the myocardium sometimes accommodates itself to the altered conditions, and may even tolerate the effort with comfort. It is, in fact, a matter of readjustment.

During an attack of angina major, in addition to the terrible crushing agony substernal in site there are accompanying pains or unpleasant sensations which may be felt in the back between the scapulae, in the shoulders, arms, neck (suprasternal notch), jaw, even in the face and eyes. So in milder angina these radiated pains are to be noted, and they may prove of the greatest help in recognizing and assessing the significance of indefinite substernal discomfort.

The difficulty in diagnosis is increased when there is an entire absence of complaint of pain or tightness in the chest. In most instances, however, cross-examination will elicit the presence of some such substernal discomfort if the effort inducing the attack is unwisely persisted in. As an example of this the following case may be quoted.

## CASE I.

In December, 1923, a man, aged 69, complained of severe neuralgic pain in the neck. The pain was crushing in character and situated in the suprasternal notch. It had occurred on several occasions in the two months before his visit. The teeth had been suspected and one extracted, but the pain recurred. It was brought on chiefly by exposure to cold, and also (although not so noticeably) by walking or effort. It was relieved by a hot drink or by going into a warm room. It did not radiate either into the back, or shoulder, or arms, but if he persisted in walking, or in whatever effort he was undertaking at the time, he developed an aching pain behind the manubrium. This important fact was only extracted by persistent cross-examination. Pain was also brought on by getting out of a warm bath and during the unavoidable exposure while drying himself.

He was firmly convinced that the trouble was in his throat, and he had seen several throat men, who had been unable to give him any relief. His throat was normal. There was some arterio-sclerosis, such as one would expect in a man of his age, and the blood pressure was normal.

I class this man as an angina minor of an eccentric type. Two other rather similar cases will further illustrate this point.

## CASE II.

A man, aged 65, was first seen by me on March 13th, 1925. He complained that he had to stop when walking because of a peculiar feeling in the epigastrium. Persistence in walking caused salivation. Occasionally he experienced a sense of pressure in the chest behind the sternum, as if something within was pressing outwards. These symptoms were always more easily induced after a meal. He was a spare man, and was never seriously ill. There was a moderate degree of arterio-sclerosis. Blood pressure 185/110 mm. Hg. The symptoms were first noticed six years before he consulted me, but had been much worse during the last nine months.

On April 27th, 1926 (a year later), his condition was satisfactory, but he was still liable to the above symptoms.

The following is an interesting example of eccentric angina of a minor grade.

## CASE III.

A male, aged 59, first seen on March 17th, 1924. In this patient walking induced an aching neuralgic pain in both gums, first the lower jaw and then the upper. The pain was more liable to come on when he went out into the cold air or "of an evening with the little dawg." Pain, first felt in the jaws, was next experienced in the epigastrium—"like unto indigestion"—and was associated with a feeling of complete exhaustion and collapse. All these symptoms vanished in a minute or two if he stood still.

He first noticed pain in the jaws three years previously, and on the advice of his doctor every tooth in his head was removed. This was followed by considerable improvement, although the pain in the jaw was still occasionally felt after effort. Six months ago, however, it was as severe as ever.

On examination there was no evidence of valvular disease; there was very marked emphysema, and the voluminous lungs made it impossible to determine the size of the heart. He had definite arterio-sclerosis; a blood pressure of 160/85 mm. Hg; cardiac rhythm normal.

These three cases are exceptional, but they serve as examples of erratic manifestations of angina minor.

A more common form of related or erratic pain is a dull ache or cramp in the shoulder or arm. This is usually described by the sufferer as neuritis or rheumatism, and when it occurs—as it not infrequently does—without much, if any, pain in the chest, it is misleading and its significance tends to be overlooked.

The most important feature in all these erratic or eccentric anginas is that the pain, wherever it may be localized—neck, face, wrist, shoulder—is brought on by effort or exposure to cold, and is relieved by rest and warmth. The "indigestion" and the "rheumatism" in the arm or shoulder are both dissipated by cessation of effort.

It is to be remembered that accompanying these substernal sensations of angina minor there is sometimes a peculiar psychological disturbance—an uncanny intangible sense of foreboding, a vague dread, a recognition that there is something fundamentally wrong, an apprehensiveness which may persist long after the symptoms have disappeared. This peculiar anxiety, which does not indeed attain to the *angor animi*, the sense of impending death, accompanying the major seizure, bears no relation to the degree of pain or discomfort, but is most suggestive and characteristic; Sir Clifford Allbutt regarded it as adding definitely to the gravity of the prognosis.

## EXAMPLES OF ANGINA MINOR.

As fairly typical examples of angina minor I will relate briefly the following cases.

## CASE IV.

A man, aged 64, complained of gripping pain of moderate intensity and a sensation of pressure, unaccompanied by any dyspnoea. The pain was substernal, at the level of the third space, and covered an area the size of a crown. It was induced by walking and ceased at once when he stood still. If he persisted, pain and numbness appeared in the left forearm and hand. He had suffered in this way for two years, and had been under continuous treatment for "indigestion."

## CASE V.

In another patient, a man aged 56, the first indication of trouble dated back to December, 1920, and consisted in pain across the chest at the level of the nipples, brought on by walking up a slight incline. If he stood still it subsided. It ceased to trouble him, but recurred in March, 1921, when it was looked upon as "indigestion," but, as his doctor said, a diagnosis made "with mental reservations." A fortnight later he had five attacks of severe angina arising in the same area, and accompanied by pain extending from the tip of each shoulder down the arms to the thumbs. He thought he was dying during the acme of the attack, and was left emotional and depressed.

## CASE VI.

In April, 1923, a male, aged 52, complained of dull aching pain in the upper chest. The pain was situated just below each clavicle in the nipple line. When the pain was more severe it was accompanied by an uncomfortable feeling down the inner side of each upper arm and in the front of the forearm. It sometimes attacked him in the bathroom when dressing, and was described by him as an intense heartburn, a "hot pain." He often suffered on the way to the station in the morning, and the pain would last about ten minutes. It was relieved by rest, by the eructation of wind, and at times by stretching his chest. This pain was never agonizing. He had first noticed it in 1921 after an operation for rupture. He soon recovered and led an active vigorous life without discomfort.

The pain recurred two weeks before he consulted me in 1923, and I then found a heart moderately enlarged; blood pressure 180/100 mm. Hg; no valvular disease; no dilatation of the aorta; aortic second sound accentuated; only a moderate degree of arterio-sclerosis. Heart rate 72 and regular. He was a thin, spare, active man, and experienced no dyspnoea on exertion. I classed him as a case of angina minor. He improved considerably under treatment, but was always liable to pain if he hurried, especially after breakfast.

In October, 1924, he was awakened at 5 a.m. by very severe substernal pain radiating into the armpits. The pain extended the whole length of the sternum and radiated into the shoulder and into the arms. The blood pressure had fallen to 150/85 mm. Hg, and a soft mitral systolic murmur had developed.

I did not see him again. He died suddenly in March, 1926, in a cab, five years after the first appearance of the minor angina. With the exception of the severe attack of pain which awakened him in October, 1924, he gave no history of anything which could be called a major attack.

## CASE VII.

A heavily built, florid man, aged 60, first noticed slight sub-sternal pain six years ago at the age of 54. It was mid-sternal and was brought on by walking, especially if the day was cold. Although a medical man he did not attach any importance to this suggestive symptom until 1924—that is, two years ago. Then the pain became more severe and for the first time extended into both arms and forearms.

In November, 1925, he suffered from a frank agonizing attack of anginal pain which lasted some hours and mainly affected the lower third of the sternum.

On examining him, shortly after his attack, there were no objective signs of disease, except slight enlargement of the heart which extended 4½ inches to the left of the mid-line. The sounds were normal and the blood pressure 140/90 mm. Hg. Heart rate 72, regular. There was little, if any, dyspnoea on effort. The attacks were relieved at once by rest or a draught of whisky.

This patient died in a major attack in February of this year. Minor angina was present for four years before the true significance of the symptoms became apparent.

## CLASSIFICATION.

Following Sir James Mackenzie, I think the most satisfactory classification is that into two groups; (1) anginal pain due to some essential disease of the cardio-vascular system, which he has termed primary angina; and (2) the second group in which all evidence of such cardio-vascular disease is absent, but where there is some factor outside the circulation which has caused a lowering of the threshold to pain, or which has depreciated the efficiency of the myocardium. The neurasthenic group, I think, might be viewed as belonging to the secondary anginas.

The chief pathological changes in the primary anginas are diseases of the myocardium, with or without frank coronary narrowing; arterio-sclerosis, with or without high blood pressure; and lastly, valvular disease, more particularly of the aortic orifice, often associated with aortitis. In this group the myocardium is frankly handicapped, and it is clear that, with the exception of the syphilitic cases and those with high blood pressure, treatment cannot be expected to produce much change in the pathological condition, which is progressive in character.

In the secondary group of anginas the possible adverse factors are numerous, including subinfections or other causes of toxæmia. The nervous instability of the climacteric is associated with the lowering of the threshold to pain. Prolonged worry, anxiety, overwork, or any factor causing neurasthenia, may bring about a similar sensitiveness to painful stimuli.

It is well to remember that in a patient with definite cardio-vascular disease correctly classed as primary angina there may be present in addition conditions which would in themselves cause secondary angina, and in prognosis such possibilities must be carefully reviewed.

## INVESTIGATION OF THE PATIENT.

After careful cross-examination of the patient in regard to the pain, and after having decided that it is cardiac in type and entitled to the designation of angina minor, he must then be investigated in order to determine the presence or absence of cardio-vascular disease.

The whole cardio-vascular system must be passed under review in order to determine first whether a diagnosis of primary angina is justifiable, and the extent of the damage. Any enlargement of the left ventricle is significant. This is most marked in patients with unduly high blood pressures, although it is found also in those suffering from free aortic regurgitation, and again sometimes in the absence both of raised blood pressure and aortic regurgitation. The fair inference in the latter case is that there is depreciation of the myocardium, probably due to coronary disease.

When there is valvular disease it is practically always the aortic orifice that is affected. In an analysis of 309 cases of angina pectoris made in 1923, only 35 showed disease of the valves, and, with one exception, the aortic valves were damaged. There was definite aortic regurgitation in 26, and some degree of aortic obstruction in 10 patients. Only one suffered from frank uncomplicated mitral stenosis. If there is an aortic leak it is often slight and the patient does not present the typical clinical picture of free regurgitation. The symptoms in such patients are not those of valvular disease with cardiac failure, they are the symptoms of angina, and not to be distinguished from

the symptoms found in those other anginal patients in whom the aortic valves are competent.

Arterio-sclerosis is a common feature, as is to be expected when the age incidence of angina is remembered, and the condition of the arteries should be noted, especially those of the retina; and when possible the aorta should be x-rayed.

It is important to note the height of the blood pressure. It is unduly high in about half the cases. In 40 per cent. I have found it at or over 180 mm. Hg, and some amelioration of the symptoms is to be expected when the hypertension is modified. A marked rise in the diastolic pressure is of especial significance. Any drastic reduction of a raised blood pressure is, however, unwise in the interests of the patient, even if such a reduction can be brought about and maintained.

It is rare to find any change in the fundamental rhythm of the heart. Premature beats are not uncommon. Auricular fibrillation or the disorderly rhythm when it occurs may diminish the intensity of the pain, or even abolish it, but this is not invariably the case. In the following patient, on the contrary, the advent of fibrillation was accompanied by an increase in the liability to pain.

## CASE VIII.

A man, aged 71, complained of gripping pain in the chest, brought on by walking. He had first noticed it five weeks before consulting me in January, 1925. It extended from the second rib to the xiphisternum and out as far as the nipples. On one occasion it was accompanied by "rheumatic pain" in the front of the left upper arm from the shoulder to the elbow. The pain came on four or five times a day; it was always induced by effort, and there was no dyspnoea. The heart was normal in size and free from valvular disease. The blood pressure was 140 mm. Hg, systolic. The rhythm was regular with an occasional premature beat.

He did well under treatment until May, 1925, and then the pain recurred and was more easily induced than in 1923. It also spread down to the finger-tips. In July, 1925, the only difference to be found on physical examination was that the auricles were fibrillating, and that the ventricular rate had increased to 120 per minute.

In this man the appearance of fibrillation was accompanied by an accentuation of the pain and not, as is more commonly the case, by an amelioration of the symptoms. He died in November, 1925, in a typical attack of agonizing angina.

If space permitted I could quote other similar cases, but these will suffice.

In the examination it is of importance to determine the factors which induce the pain, more particularly the nature and severity of the effort—that is, to estimate the amount of cardiac reserve; not only the cardiac response to effort should be noted, but the constancy of that response. It is satisfactory to find in any patient that there are days when he can do with ease that which on another day causes pain, for such patients prove more amenable to treatment.

There is something sinister about an anginal pain which invariably appears at the same fixed point on ascending an incline—at the same lamp-post, so to speak—and yet it is even more ominous when there is a steady diminution of the distance that can be walked without pain or discomfort.

When there are apparently no clear evidences of cardio-vascular disease, a careful survey should be made of the patient to discover, if possible, anything which may be lowering the threshold to pain. First, any toxic cause, such as a grumbling appendix, oral sepsis, sinus disease, or some pulmonary, renal, or alimentary disorder; further, worry, anxiety, overwork, or insufficient sleep, are quite likely factors. When some such cause is responsible for lowering the threshold to pain, it persists between the attacks of pain, and in consequence the patient is not normal even when quite free from angina. He is found to be toxic, or depressed and irritable, and shows the usual indications of nervous exhaustion.

When possible, as a final feature in the examination, it is well worth while to take an electro-cardiogram. This may reveal evidence of myocardial damage which might otherwise escape recognition. I will refer later to its value in prognosis.

## DIAGNOSIS.

In the absence of syphilis or valvular disease of the heart, primary angina is rare under the age of 45, and it is

## ANGINA MINOR.

unwise to make such a diagnosis in the young if neither aortic disease nor an abnormal blood pressure is present. In fact, the diagnosis must be made on the character of the pain and not on the physical findings. Too often a correct diagnosis of angina is refused because on physical examination either nothing abnormal is found or there is only a moderate degree of enlargement. It must be remembered, before passing a heart as normal, that emphysema masks an increase in the size of the heart, and also makes it difficult to recognize any abnormality in the heart sounds.

Pain in the region of the heart is a common complaint in most patients with valvular disease, and in many others, especially in young males presenting the symptoms of the "effort syndrome" (the D.A.H. of army days). But this pain, though cardiac in origin, is not entitled to the label "angina." In this group the pain is submammary and often felt directly over the cardiac thrust. It may be stabbing, or an ache, and the skin and muscles of the adjacent areas are often tender on palpation, especially directly over the apex beat. Hyperaesthesia is much more noticeable in these patients than in the anginas.

Although usually induced or aggravated by exercise, the pain is often quite independent of effort and frequently occurs when the patient is in bed; and it may be accompanied by troublesome palpitation. If the pain does extend into the arm it is nearly always diffuse, and frequently the whole arm, and often both arms. It is less likely to have the segmental distribution or the characteristics of anginal pain. Occasionally it extends from head to foot, limited to the left side, and when the pain is bad there may be great nervous excitement—sometimes even nervous rigors—followed by a condition of prolonged nervous prostration. This is in great contrast to a primary angina, where cessation of an attack as a rule leaves the patient comfortable and free from physical distress.

The following is an example of cardiac pain which presents the characters of a secondary angina and which had been looked upon as major.

## CASE IX.

A nurse, aged 30, was examined on April 9th, 1926. She was tall, with red hair, and a healthy complexion, and was alarmed and anxious about her heart. She complained of pain just to the left of the sternum in the fourth intercostal space. It was as if something was pressing hard on the chest. It caused her breathing to stop, and radiated into the left arm, involving the whole arm from shoulder to wrist in a cramp-like pain. The pain was induced by effort, or annoyance. Examination showed a heart normal in size and sounds, free from any indication of disease. Blood pressure 125/75 mm. Hg. Heart rate regular. The heart sometimes raced at 100 to 120. Ever since she has been liable to two and a half years before. Ever since she has been liable to vasomotor blotching, and her hands have been blue and cold in the winter. In addition to dyspnoea, she becomes dizzy and faint on climbing the stairs, she wakes in the night with a sensation of shortness of breath, which sometimes lasts for ten to thirty minutes. The attacks are always worse after she has been nursing a "bad case," and also after a period of excitement, but not while excited.

There are certain features in this patient which are very suggestive, and indicating that there are factors outside the heart; the vasomotor system is unstable, and the effect of any nervous exhaustion is noticeable.

## THE OUTLOOK IN ANGINA MINOR.

The prognosis is admittedly difficult when the patient is afflicted by major angina; it is doubly so when the symptoms are of the slight, transient, mild degree present in angina minor. The great danger is that of a wrong diagnosis. The anginal element in the complaint is wrongly interpreted, until the "grand mal" stage arrives, and the diagnosis is "writ plain for all the world to see."

In angina minor the prognosis must be based on a consideration of the same facts as in angina major. It is the integrity of the myocardium and the soundness of the arterial tree that matters, and, of course, primary angina of the minor type is more serious than secondary angina minor.

The more reasons there are for believing that the threshold for pain is below normal, the better the outlook, and when the causes for the lowered threshold to pain can be removed there is still further reason for a tempered optimism. Subinfections, mental worry and strain, insuffi-

cient sleep, and factors of this kind can be treated, removed, or neutralized. The prospect brightens in so far as this can be carried out satisfactorily.

It is not wise to venture on any prognosis when the pain dates from a recent pyrexial attack such as influenza. The myocardium may take some months to recover from the transient toxæmia, and during the convalescence the symptoms may be misleading. Persistence in the liability to pain and discomfort in spite of treatment with it there is factory feature, especially if combined with the gravity of the clear evidence of cardiac embarrassment accompanied by enlargement of the heart. A high blood pressure, peculiarly enough, does not appear to add to the gravity of the prognosis. My figures for all anginas gave the average duration of life from the first appearance of pain as four and a quarter years in the high pressure cases (180 mm. Hg and over), and three and a half years in these patients there was a year or two when the symptoms were of the mild minor type, before major angina developed. I feel inclined to view the minor angina with low blood pressure as probably less satisfactory than when the pressure is high.

When there is a clear history of syphilis the prognosis should be guarded until a full course of antisyphilitic treatment has been carried out, for occasionally the improvement to attacks was diminished and the duration of life prolonged by vigorous antisyphilitic treatment in anginas of syphilitic origin. My experience definitely corroborates this. Potassium iodide in massive doses is not enough; the patient should have two courses of intravenous arsénobillon and prolonged mercurial treatment.

The family history is always worth considering when reviewing the prognosis. The tendency to hyperpæsia is sometimes a family characteristic, and in such families death is common from angina, cerebral hæmorrhage, or cardiac defeat. With such a family history the expectation of life is poor over 50, and the mere grumbling of angina minor is exceptionally ominous. At times the electro-cardiograph findings indicate a speedy exit, especially when they reveal the presence of a bundle branch lesion. Even when there is no evidence of a bundle lesion other well recognized deviations from the normal may be met with which have a sinister significance. The following case is of interest in this connexion.

## CASE X.

In May, 1925, a medical practitioner, aged 60, complained of a "raw feeling" across the upper sternum, described by himself as pleurodynia, which he did not view with any apprehension. This sensation was noticed on going out of the house. Exposure to cold or damp would bring it on, but in a warm room he felt no discomfort. It did not interfere with his breathing. He had never been ill in his life, and this was the first time he had ever consulted a doctor. He had only noticed this queer sensation for four weeks.

On examination the pulse was 84, regular, not perceptibly collapsing. Arteries just palpable. Blood pressure 170/55 mm. Hg. The heart was 4 inches to the left of the mid-line; there were no thrills. Over the aortic area I heard a to-and-fro bruit, and the aortic second sound was not audible. A soft diastolic murmur conducted towards the apex could just be heard. The urine was normal. On May 22nd an electro-cardiogram demonstrated a right branch bundle lesion. The blood pressure had dropped to 135/55 mm. Hg. The heart rate was 84, regular and normal.

On June 7th he had an attack of major angina which killed him in a few minutes. The total duration of life from the first indications of minor angina was only eight weeks.

## TREATMENT.

My remarks on treatment must be brief. In the *Lancet* of November 8th, 1924, I discussed this fully, and the general principles indicated there apply with equal force to the minor form of angina, and, it might be added, with a fairer prospect of satisfactory response.

A damaged heart necessitates a sheltered life, and the reasons for the restrictions advised should be frankly explained to the patient. His full co-operation is imperative, and he must face his limitations and live within them. The efficiency of the myocardium must be maintained by adequate rest, a regulated life, and such medicinal measures as hæmatinics. When syphilis is an etiological factor, appropriate and efficient antisyphilitic treatment is, of course, imperative.

Since the work of the heart bears a relation to the body weight, an attempt should be made to bring the bulk of the body, when it is excessive, within normal limits. Careful dieting to obtain this result should be carried out and the results noted. An abnormally high blood pressure can sometimes be modified with definite relief to the overloaded myocardium.

Much can be done in the secondary anginas when by meticulous cross-examination the cause of the lowered threshold to pain has been discovered. All possible sources of persistent low-grade infections should be investigated and radically treated—dental sepsis, sinus disease, abnormal intestinal conditions, pyelitis, chronic appendicitis, etc.

An attempt must be made to eliminate worry and make sure of sleep. For this a mixture of ammonium bromide and phenazonum is especially helpful. In the readjustment of the patient's life, factors giving rise to mental strain and irritations should be obviated as far as possible.

As my last word, may I lay stress again on the very great importance of an early diagnosis when the symptoms, though but slight and elusive, are both ominous and sinister. An accurate diagnosis *then*, followed by wise treatment, offers some chance of arresting, or at any rate of retarding, the development of the pathological changes responsible for angina.

## THE ACTUAL PLACE AND FUNCTION OF THE TUBERCULOSIS DISPENSARY IN THE TUBERCULOSIS SCHEME.\*

BY

SIR ROBERT PHILIP, M.D., LL.D.,

PROFESSOR OF TUBERCULOSIS IN THE UNIVERSITY OF EDINBURGH.

When the council honoured me with the request to open this discussion I accepted with alacrity. The fascination of tuberculosis has held me a bondsman throughout my professional life. The range of interests is always widening. In offering a few thoughts for your consideration it will be my endeavour to do so briefly and simply, in the hope that it may stimulate members of the Conference to give us freely of their experience.

### Forty Years Ago.

It is difficult to-day for the man in middle life—and still more for the younger man—to realize the attitude of mind towards tuberculosis which prevailed forty years ago and previously among both doctors and laymen. What was then accepted as care and treatment is now hardly imaginable.

The victim of tuberculosis—so-called consumption—was for the most part recognized too late. He was generally expected to die. The treatment meted out to him was empirical, unphysiological, and usually futile. The vain attempts at protection tended to hasten the end. With the death of the patient the interest that had been kindled by his illness was extinguished.

Speaking of the expectancy of life of the consumptive patient, Dr. C. J. B. Williams, in his treatise on *Pulmonary Consumption* (1871), says, with reference to the first ten years of his practice, 1830-40: "My general recollection of the histories of the developed disease at that time is that of distressing tragedies, in which no means used seemed to have any power to arrest the malady; and life was rarely prolonged beyond the limit of two years, assigned by Laënnec and Louis as the average duration of the life of a consumptive."

### Conception of Tuberculosis Dispensary (1887).

Let me try to recall some of the circumstances and events which led to the remarkable alteration of outlook and action which now prevails.

It is some forty years since, following on the discovery of the essential cause of tuberculosis, its infective nature came to be admitted. While engaged in laboratory

work on tubercle, and attached to a general medical dispensary, it was borne in on me that acceptance of the infective nature of the disease carried with it far-reaching consequences. It seemed clear that, the infective nature of tuberculosis being granted, the principles which had been effectively applied in relation to other infective conditions were, with appropriate modifications, applicable to tuberculosis likewise.

Apart from a few special hospitals devoted to diseases of the chest, the chief avenue to care and treatment open to the poorer citizen suffering from tuberculosis forty years ago was by way of the out-patient department of a general hospital or similar medical institution. What happened daily in out-patient departments amounted to this—that the patient, suspected to be suffering from what was then spoken of as consumption, was examined for the presence of certain recognized signs of chest disease; when such were ascertained to be present, the sick man was accorded a prescription for his cough or other chief symptom, and commonly for cod-liver oil, and was invited to report himself from time to time for similar consideration and treatment. Occasionally he was passed on for admission to hospital, when such facilities were available. The number of special beds at that date was extremely scanty, and he was not very warmly welcomed in the general wards. The demand on beds was out of all proportion to the number of tuberculous applicants, with the result that even the small percentage which attained admission enjoyed the available benefit for a relatively short period. There was little serious effort to ensure anything more than amelioration or arrest of existing symptoms. The infective nature of the disease hardly came under review; nor were the facts of the illness linked in any close fashion with the conditions of the patient's home and household.

All this was radically wrong. It involved a disregard of the natural history of the disease, its infective origin, its widespread distribution, its lengthy course, its protean manifestations, its dependence on environmental conditions, its tractability when efficiently handled for a sufficient period, and many other facts which we now regard as commonplaces.

Reflection on such lines led me to press for a wider conception and fresh line of procedure. The proposal culminated in the establishment of the tuberculosis dispensary in 1887.

### Purpose and Programme.

The essential purpose was the creation of a centre towards which patients suffering from this infective disease, and the friends of patients, and the public, could readily turn for every sort of direction and help, and from which there would radiate information of many kinds for the guidance of individual patients, households, and the community as a whole.

The original aims of the tuberculosis dispensary have been often detailed. They are so well known that on the present occasion there is little need to recapitulate them in detail. They constituted the first attempt to hunt down the infection, to discover the haunts and methods of the invader, and to raid him on his own territory. The principles and methods were incorporated in the well known circular of the Local Government Board of Scotland, dated March 10th, 1906, which reproduced in *extenso* a paper given by me to the International Congress at Paris in 1905. The principles and methods were frankly accepted in 1905 by the Departmental Committee on Tuberculosis (1912), which adopted the programme of the Edinburgh Tuberculosis Dispensary as a model for the tuberculosis dispensaries of the country.

The Departmental Committee, in describing the functions of the tuberculosis dispensary, affirmed that it should serve as (1) receiving house and centre for diagnosis; (2) clearing house and centre for observation; (3) centre for curative treatment and supervision of ambulant cases; (4) centre for the methodical examination of contacts and the investigation of environmental conditions; (5) centre for continuous care of patients—so-called "after-care"; (6) information bureau and educational centre. The Departmental Committee placed the tuberculosis dispensary

\* An address introductory to a discussion at the twelfth annual Conference of the National Association for the Prevention of Tuberculosis, Glasgow, July 1st, 1926.

as the first unit in the tuberculosis scheme and confirmed the view

"that the tuberculosis dispensary should be the common centre for the diagnosis and for the organization of treatment of tuberculosis in each area, at which the various bodies and persons connected with the campaign against tuberculosis should be brought together. The aim should be that no single case of tuberculosis should remain uncared for in the community. . . . The tuberculosis dispensary should be linked up to those institutions (hospitals, sanatoria, farm colonies, open-air schools) for which it will act as a clearing house."

### Larger Results.

For the moment we are less concerned with the original purpose but rather with results which have emerged and developed from the continuous application of the methods proposed. Forty years constitute a period of sufficient length to enable us to appraise the significance of the activities.

At the outset you will allow me to say that, great as seemed the possibilities at the start, appreciation of their extent and value has grown with each succeeding year. A few of the more conspicuous developments may be cited.

1. *Widespread Distribution of Tuberculosis.*—The tuberculosis dispensary has demonstrated, as no other agency could, the extensive ramifications of tuberculosis throughout the area served by the dispensary. It has collected living proof of the universality of maps showing intervals of tuberculosis, taken at successive intervals throughout the area, demonstrates that the more an area is thoroughly investigated, the more is the population found to be permeated by the tuberculous taint. It has shown further that different portions of a given area differ in degree of saturation. It has thus thrown a flood of light on the influence of environment as a factor in the production and maintenance of tuberculosis.

2. *Spread through Households.*—By the systematic examination of households—the "march past" of the taint—it has afforded incontrovertible evidence of the spread of the disease throughout a household from a primary source of infection.

3. *Infection in Childhood.*—It has emphasized the frequency with which tuberculosis is contracted in childhood. In household after household it has determined the existence of tuberculosis in the majority of the children by systematic search in one family circle alone.

4. *Heredity.*—Its investigations have dealt a serious blow at the doctrine of heredity—fondly cherished as that the natural history of the disease. The investigations offer strong support to the applicability of the views based on the observations of Bang and others in cattle, to the effect that the tuberculous mother very seldom produces offspring already tainted by tuberculosis, and that the offspring of such mother is saved from the risk of infection from the mother in proportion as it is protected by separation from her, while, conversely, the risk of early contraction of tuberculosis is accentuated in proportion as close contact with the infected mother—or with other infected member of the group—is maintained. Tuberculosis is thus seen to be a family or household disease, not because of hereditary transmission, but because of the abundant opportunities afforded for the transmission of infection from one infected individual to the other members. This risk exists in high degree in the earliest years of childhood.

5. *Recognition at Earliest Moment.*—The system of examining contacts has not only detected many cases that otherwise would have been missed. It has also afforded opportunity for the very early detection of infection as it occurs in successive additions to the household. It has shown how it is possible by careful observation of infection in a growing family the actual advent of infection in successive children. In this way it has rendered possible the practice of anticipatory treatment—that is, of treatment, antigenic or other, which has in view the raising of the resistance of the infected individual with a view to preventing the worse consequences of such infection.

6. *Continuity of Observation.*—The dispensary has thrown a flood of light—by its continuity of treatment and care—on the natural history of tuberculosis. It has

enabled the observer to follow the child from the moment of recognized infection throughout a long period of years. In this way it has been possible in my own experience to observe the same infected individual throughout twenty to thirty years and longer.

7. *Natural History of the Disease.*—By this means it has been possible to construct a picture of the successive manifestations which most commonly repeat themselves in the evolution of tuberculosis. It has shown that in the vast majority of cases there is a gradual extension—just as in the experimental animal—from the point of primary infection by way of the lymphatic system, until the deeper viscera are successively involved. The dispensary has thus served to illuminate the relation of pulmonary tuberculosis and the more likely points of entrance of infection, and has relegated pulmonary disease to its proper place as constituting for the most part a relatively late visceral involvement.

8. *Continuity of Infection.*—Observations at the dispensary have shown, not only the continuity, but the varying manifestations of the tuberculous process in the same individual throughout a long series of years. It has revealed the ebb and flow in the progress of infection throughout a long life. It has shown how cases in the so-called third stage of pulmonary disease—with cavity formation which used to be regarded, and is still regarded by many, as the terminal picture—may yet live and go comparatively strong for thirty years or longer. It has illustrated how a cavity, especially when it occurs in young subjects, may, during the process of growth and development, gradually contract and finally disappear.

9. *Necessity for Long Supervision.*—By continued observation on ambulant patients and on those who have undergone sanatorium or other institutional treatment, the dispensary has proved how essential is the prolonged maintenance of such supervision, and how valueless may be the result of short periods of residential treatment—as, for example, the classic three months in a sanatorium, mere snippets in relation to the time limit necessary for the establishment of sound and effective arrest by the necessary histological changes.

10. *Economy in Treatment.*—Continuous, prolonged supervision at the dispensary has demonstrated how much can be done for tuberculous patients by ambulant treatment. From the records abundant proof may be had of how health may be maintained successfully without much expenditure. By means of weekly, fortnightly, or monthly guidance received at the dispensary, large numbers of patients may be kept on their feet and successfully treated without recourse to the sanatorium, or following on sanatorium treatment—and this at a minimum of cost.

11. *Housing: Reform in the Home.*—By a sound system of domiciliary visitation, the dispensary has succeeded in reforming homes and households, reducing the effects of unhealthy environment and recreating insanitary houses after the image of the sanatorium. In this direction the dispensary's educational value to a community through doctor and nurse can hardly be overestimated. These examples of the far-reaching activities of the tuberculosis dispensary might be multiplied. They are cited more as illustrations. Others will emerge in the course of the discussion from able men who, in town and county, have had many years' experience in developing and refining this significant instrument of preventive medicine.

What the Tuberculosis Dispensary should not be. In drawing these desultory remarks to a close, a few words seem desirable on the other side of the picture—namely, what a tuberculosis dispensary should not be.

The establishment of the tuberculosis dispensary was a reaction from the comparatively ineffective out-patient department of the past. Splendid work has been effected by tuberculosis officers in different parts of the country; yet visits to not a few dispensaries, and extended inquiries in different directions, constrain me to the view that the ideal of the dispensary and its great possibilities are not realized everywhere.

It is unfortunately common to find that the tuberculosis dispensary concerns itself solely or chiefly with cases of

JULY 10, 1926]

# HYPOGLYCAEMIA DUE TO INSULIN IN CHILDREN.

pulmonary tuberculosis, although these constitute for the most part a late manifestation of the infection. Even then the investigation of the patient lacks reality and thoroughness. The idea of using the pronounced case of infection as a clue to the earlier—the conception of hunting down the infection in the households of the area with a view to its eradication—is overlooked or ignored. The opportunity of the dispensary as a field of fresh observation in many directions is entirely lost. With so limited an outlook the work tends to become routine. Such procedure cannot be expected to lead us very far towards the final goal. As I ventured to say on a previous occasion:

"The calm repose of the physician who, stethoscope in hand, decides for or against a cavity in the lung, and then contents himself with prescribing cod-liver oil, and perhaps a chronic pectoral mixture, must be disturbed. His cerebration and locomotion both require stimulation, so that he may be led to anticipate the disease by earlier diagnosis, and to determine the potentialities of contagion in the home. With the infection detected he must leave no stone unturned in the study of the patient's life-history and environment, which may throw light on causation or maintenance of disease. Chiefly must the physician concern himself with the health of the rest of the household. The whole family—or as many members as possible—must be scrutinized with scientific suspicion. 'The patient will not be sent home merely rich in weighty counsels. He will be followed to his home by doctor and nurse with trained eye and skilled finger, prepared to observe and sift every fact and to hold a critical 'march past' of the household. That is the way to raid the haunts of the tubercle bacillus effectively."

## Searchlight Installation.

Ernest Renan compared the human conscience to a light-house with recurrent flashes of illumination which guide the uncertain mariner on the sea of life. I like to think of the tuberculosis dispensary as a searchlight installation in the vast tubercle-tainted plantations of our communal life.

In proportion as the installation is complete and the operators are understanding, results will surely follow. The instrument suffuses with light the area of operations so that no facet of the problem remains in shadow. It superilluminates every case of tuberculosis and ensures a just appreciation of its character and bearings. The penetrating ray enters the home and, linking effect with cause, brings the means of healing and the assurance of prevention to each of the dwellers.

And, throughout the area thus illuminated, watchful observers "battling with custom, prejudice, and disease," may yet snatch further triumphs and gather new facts and ideas of which, to-day, we hardly dream.

# HYPOGLYCAEMIA DUE TO INSULIN IN CHILDREN.

BY

G. A. HARRISON, B.A., M.D.,\*

BIOCHEMIST, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON.

It is not widely known that the level of blood sugar at which symptoms of hypoglycaemia occur is decidedly lower in children under 12 years of age than in adults. There is some variation in the level at which symptoms arise following insulin administration in adult diabetics. This is observed not only when comparing one patient with another, but also in repeated observations on the same patient. In my experience the level of blood sugar when hypoglycaemic reactions occur in the adult usually lies between 60 and 80 mg. per 100 c.cm., though very occasionally values as high as 100 and even 110 or 130 mg. or as low as 50 mg., have been encountered at the time of the reaction. Anomalous results (outside the range of 60 to 80 mg.) have been experienced too often now to be explicable solely on the basis of analytical errors. It is possible that the rate of fall of the blood sugar is of more consequence than the actual level in determining the onset of symptoms, though I have not uncommonly met with rapid falls (for example, from 328 to 55 mg. per 100 c.cm.

\* Working on diabetes with a grant from the Medical Research Council.

in five hours) without resultant symptoms. Another possible explanation is that it is the concentration of sugar in the central nervous system that matters, and this sugar content of the peripheral blood may be either above or below this critical value in certain circumstances.

In eleven diabetic children, aged 1 to 11 years, treated with insulin, twenty-eight analyses out of some hundreds showed a blood sugar of less than 50 mg. per 100 c.cm. without any concomitant clinical symptoms of hypoglycaemia. The lowest value was 28 mg., and the average of the twenty-eight analyses 39 mg. In three additional records (29, 44, and 45 mg. respectively) there were slight symptoms only. On thirty occasions in the above cases values between 50 and 59 mg. were found in the absence of symptoms. Typical examples follow. All analyses were made by Maclean's method, and in duplicate.

Case 1.—Male, aged 1 year and 2 months. Blood sugar on admission 442 mg. per 100 c.cm. On the third day of insulin treatment the blood sugar was 32 mg. four hours after the morning injection of 10 units, but there were no signs of hypoglycaemic reaction. Before the injection the blood sugar was 244 mg. The diet at this time consisted of 24 oz. of milk daily. On six subsequent occasions the blood sugar was reduced to values between 28 and 49 mg. per 100 c.cm. some three to five hours after 6 units of insulin, without any signs of a reaction. On another occasion there were definite signs of hypoglycaemia. The baby was pale and slightly drowsy. He tended to fall forward, burying his head in the clothes. Blood analysis yielded the figure 44 mg. sugar per 100 c.cm. Five grams of carbohydrate (orange juice) restored the patient to normal.

The low levels of blood sugar are striking in this baby. As in adults, the level at which clinical signs occur is not a fixed point. On one day there were definite signs with a blood sugar of 44 mg., on another no signs of a reaction with a blood sugar of 32 mg.

Case 2.—Female, aged 2 years and 1 month. The daily diet contained 37 grams of carbohydrate, 31 grams of protein, and 50 grams of fat; 10 units of insulin were given daily. There were no signs of hypoglycaemic reaction on seven occasions on which the blood sugar varied from 32 to 49 mg. per 100 c.cm. There were slight but definite signs (pallor and extreme hunger) on one occasion when the blood sugar was 29 mg. per 100 c.cm.

Case 3.—Male, aged 3 years and 3 months. The blood sugar was 46 and 49 mg. per 100 c.cm. respectively on two occasions when there were no signs of a reaction.

Case 4.—Female, aged 4. Blood sugar 38 mg. per 100 c.cm. there were no signs of clinical symptoms.

Case 5.—Female, aged 6. No symptoms when the blood sugar was 49 mg. per 100 c.cm. Symptoms relieved by 5 grams of carbohydrate (orange).

Case 6.—Female, aged 9. Slight symptoms with blood sugar of 45 mg. per 100 c.cm. Fixed diet of 60 grams of carbohydrate, 70 grams of protein, and 140 grams of fat daily. He was given 8 units of insulin half an hour before breakfast, and 5 units a quarter of an hour before tea. The blood sugar results are shown in the following table. There were no signs or symptoms of hypoglycaemic reaction throughout. The boy walked to the laboratory from the ward, and "played about" in the intervals between the collections of the samples of blood.

| Blood Sugar, mg. per 100 c.cm. |                                      |    |    |     |     |                              |

| May 4th                        | —                                    | 59 | —  | —   | 156 | —                            |

that in children the blood sugar may  
adult hypoglycaemic lo  
reaction.

It will be seen that in children the blood sugar may fall some 20 to 40 mg. below the "adult hypoglycaemic level" and yet be unaccompanied by signs of a reaction. It is well recognized that the general level of blood sugar in children is lower than that of adults, and therein may lie the explanation of these observations.

There is another point of practical importance. The hypoglycaemic reaction is not nearly so well defined in children as in adults. In the younger children and infants,

of course, we are dependent solely on objective signs, and even the older children often are not able to describe their subjective symptoms as well as adults. In children the first signs of a hypoglycaemic reaction are often pallor, an unusual quietness, lassitude, and a tendency to doze whilst undisturbed; when examined, fretfulness and a greater tendency than usual to weep or cry are noted. None of these signs can be regarded as characteristic, for any or all of them may occur apart from hypoglycaemia. Sweating may or may not occur, but when it does it can hardly be regarded as a characteristic sign, sweating being not at all uncommon even in healthy children owing to excess of (bed) clothes, etc. Some writers consider that an increase in pulse rate is a valuable sign, but in my experience this is by no means constant and is not trustworthy.

#### *Treatment.*

The treatment of hypoglycaemia is well established—the administration of glucose or of other rapidly absorbed carbohydrates. The dose of carbohydrate depends on the degree of hypoglycaemia. In very mild attacks it is sometimes unnecessary even to give sugar. The patient may recover spontaneously or a cup of borrlil or hot weak tea may suffice. In more severe but still mild reactions 5 grams of carbohydrate as orange juice (45 c.cm. or  $1\frac{1}{2}$  oz.) or as orange quarters (50 gm. or  $1\frac{1}{2}$  oz.), or as one lump of cane sugar dissolved in water and flavoured, if desired, with lemon juice, are ample. If the symptoms have not obviously improved in fifteen to twenty minutes the 5 grams of carbohydrate should be repeated. Sometimes symptoms occur shortly before a meal is due; it is then often sufficient to give the meal or part of it a quarter or half an hour before the prescribed time. The exact details of treatment in any given case will depend on circumstances—whether the patient is at home or under close observation in an institution, the availability of blood-sugar determinations, etc.—but it should be an absolute rule to avoid treating hypoglycaemia with excessive amounts of carbohydrate and so rendering the patient hyperglycaemic. Of course, severe hypoglycaemic reactions demand larger doses of carbohydrate—for example, 15 grams as cane sugar (3 cubes); it may be necessary to give 15 to 20 grams of glucose by stomach tube, and this method can often be employed successfully even though the patient be semiconscious. Intravenous injection of glucose should be reserved for emergencies.

One practical point, sometimes forgotten, is that the sugar should invariably be administered in solution to ensure rapid absorption, and this is particularly important when hypoglycaemic symptoms are marked. One of my adult patients awakened one night with severe symptoms, and promptly swallowed with some difficulty two lumps of cane sugar. At the end of fifteen minutes the symptoms were worse, so she took some more lumps of sugar, and this was repeated till fifteen lumps in all had been devoured. The symptoms still persisted and she became very frightened. Fortunately she was then given some brandy and water, whereupon she came round in ten minutes. In the morning, of course, she was markedly hyperglycaemic (blood sugar 430 mg. per 100 c.cm.).

In children variation in the amount of exercise is a real difficulty, and not seldom accounts for hypoglycaemic reactions. Thus on several occasions I have been consulted by a parent who noted that her diabetic child had attacks of giddiness at the beginning of his holidays. The child played strenuous games in the garden in the holidays, whereas during term time he was seated at his lessons. Avoidance of severe exercise during the period two to five hours after insulin had been administered promptly caused the attacks of giddiness to cease. Adult diabetics soon learn to provide for unusually strenuous exercise by reducing slightly the dose of insulin, or by increasing the carbohydrate in the meal prior to the exercise; but it is much more difficult to make similar preparations in the case of children. The visit of a friend may result in a vigorous romp or in some quiet game; nobody can prophesy what will happen, least of all the child. The interference, unfortunate but absolutely necessary, with the spontaneous life of these little patients is one of the factors which make them so old for their years.

## AN AID TO THE RADIOGRAPHY OF THE MAXILLARY ANTRUM.

BY

B. McKELVIE, M.B., CH.B.VICT.,

CLINICAL ASSISTANT, THROAT AND EAR DEPARTMENT,  
EDINBURGH ROYAL INFIRMARY.

THE following method is suggested as an aid to the diagnosis of cases of choanal polypus and new growth of the antrum, where an ordinary x-ray photograph often is of little use.

It can be ascertained in these cases whether a choanal polypus is coming from the antrum, and, if it is, whether

FIG. 1.—Skiagram of normal antrum injected with lipiodol.

it is attached in the usual situation or not. If new growth is suspected, the wall from which the growth is coming may often be decided.

Lipiodol (iodine in poppy-seed oil) is injected with the Watson-Williams syringe (the ordinary Lichtwitz cannula and a Record syringe may be used) into the antrum. Since lipiodol is opaque to x rays, the less opaque growth or

FIG. 2.—New growth of maxillary antrum. Lipiodol seen in outer part of antrum outlining the growth; wool seen in nose.

polypus is outlined by the dark shadow of the injected lipiodol. If a lateral and an antero-posterior view are taken a fairly accurate idea of the position and extent of the growth can be obtained. The method is excellent also for giving an outline of the sinus and showing the extent of alveolar recesses.

Puncture is made, after cocainization, through the inferior meatus of the nose, the middle meatus having previously been packed with wet wool extending as far back as possible in order to prevent the lipiodol from escaping by way of the normal and accessory ostia if these

are not already closed by the disease. Sodium bromide was at first tried instead of lipiodol, but it was found that it was very apt to soak the wool and escape. It is also as well to apply a piece of wet wool to the puncture hole in the inferior meatus as soon as the needle has been removed, to prevent escape of lipiodol in this situation.

The lipiodol may be removed with the Watson-Williams syringe, the needle of which can be placed in the puncture hole formerly made. In other cases, as the antrum will be opened surgically later, the lipiodol may be left *in situ* till the operation, as it is sterile when injected.

The accompanying figures are reproductions of antero-posterior x-ray photographs; they show a normal maxillary antrum injected with lipiodol, and an antrum containing an epithelioma. In the latter the lipiodol has filled those parts of the antrum not occupied by the growth. The pieces of wool in the nose are well seen.

## PINNING THE FRACTURED ULNAR STYLOID PROCESS IN COLLES'S FRACTURE.

BY

FRANK J. HATHAWAY, M.D.,

SURGEON, KING EDWARD VII HOSPITAL, WINDSOR.

MANY patients who have suffered Colles's fracture complain, months afterwards, far more of weakness of the wrist-joint and pain over the ulnar styloid process than of the radial fracture. An x-ray examination of these cases shows that this is caused by a fracture and separation of the ulnar styloid process.

There is no doubt that the successful treatment of Colles's fracture depends upon accurate reduction of the radial fracture; but there are many cases, especially those of impacted fracture of the radius, in which reduction is difficult and is not always accomplished successfully without open operation, and it is in these cases that separation of the ulnar styloid process is the cause of pain and weakness in the wrist-joint, often many months after fracture. This after-result of Colles's fracture impressed me so much that I began to pin the fractured styloid process of the ulna.

Although the fractured radius may be accurately replaced, yet if x-ray examination shows the styloid process of the ulna to be still separated, open operation should be performed in order to get good bony union of the fractured surfaces, and not the fibrous union which would otherwise result. It is by this means that pain and weakness of the wrist-joint can be prevented.

Anatomy textbooks state that arising from the styloid process of the ulna is the strong internal lateral ligament of the wrist-joint, which is attached to the rough non-articular border of the cuneiform bone, some of its fibres being prolonged to the pisiform bone. It seems to me that if this strong internal lateral ligament of the wrist-joint is rendered useless by want of accurate approximation of the fractured ulnar styloid, where this separation is shown by x rays to be present the only thing to do to prevent resultant pain and weakness is accurately to approximate the fractured surfaces and pin them into position and ensure sound bony union.

In those cases of impacted Colles's fracture where reduction is impossible because the fractured lower end is caught up in the pronator quadratus muscle and open operation is necessary, then, should there also be a complicating fracture of the ulnar styloid, this too should be operated upon. Hence it seemed to me common sense that the fracture of the ulnar styloid process should not be overlooked. I have devised an open operation which is, I understand, original—it is very simple and takes only a few minutes to perform.

A vertical incision is made directly over the fractured ulnar styloid, and the fractured surfaces are exposed. They are found separated by several millimetres (as shown by the skiagram), and frequently the distal end of the fractured styloid process is so pulled upon by the strong internal lateral ligament that it is rotated as well as separated, and its base tilted upwards and towards the extensor surface of the forearm, proving that without

open operation bony union is even more impossible than it is with simple separation. (The x-ray picture will not show this tilting of the fractured tip of the styloid process.) With the thumb and index finger of the operator's left hand the fractured styloid process is accurately replaced, and, being thus held in position, an ordinary straight bayonet-shaped needle is, with a hammer, driven through the fragment into the lower end of the ulna in a direction downwards and slightly towards the flexor and radial side of the forearm. When the needle has been driven sufficiently far to fix the styloid fragment the needle is cut off with wire-clippers, the fascia replaced, and the wound sewn up. The forearm is placed on an ordinary Carr's splint for seven to ten days, after which the splint is discarded, the stitches removed, a firm bandage applied, and massage and passive movements started forthwith.

This operation is very simple and takes only a few minutes to perform, and I maintain that where, with separation of the fractured surfaces, this fracture complicates a Colles's fracture, the pinning of the styloid ulnar process should always be performed, and will prevent resultant pain and weakness of the wrist-joint. But at the same time it must be understood that accurate radial reduction is the first and foremost object in the treatment of Colles's fracture.

The x-ray photograph is from a recent case which I consider typical, because after accurate radial reduction there remained separation of the ulnar styloid process. The patient was a lad aged 16, and I feel confident that without open operation and pinning of the ulnar styloid he might have had a permanently weak wrist which would have interfered seriously with his efficiency in after-life; whereas he now has firm bony union of the fractured styloid process and as strong a wrist-joint as he had before his accident, without any pain, weakness, or deformity.

## CONGENITAL ABSENCE OF THE PECTORAL MUSCLES.

BY

H. WALLACE JONES, M.Sc., M.D., M.R.C.P.,

SENIOR HONORARY ASSISTANT PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.

PARTIAL or complete absence of the pectoral muscles is a condition comparatively frequently met with, and in a series of cases of congenital absence of muscles collected by Bing<sup>1</sup> loss of the pectoralis major (usually the pars sternocostalis) and of the pectoralis minor together was the commonest abnormality to be present (28 per cent. of the total); absence of the pars sternocostalis of the pectoralis major alone is the next most frequent type of abnormality, and was present in 9 per cent. of the cases. These figures are probably too high, owing to the fact that in the ordinary routine examination of patients this abnormality is very readily noticed, while the detection of most of the other muscular defects requires a more detailed examination.

A case of complete absence of both pectoral muscles on the one side is recorded by Severn,<sup>2</sup> but the absence of both major and minor is a very rare occurrence—usually the clavicular part of the pectoralis major remains, and often undergoes considerable hypertrophy. Absence of the

pectoralis minor unaccompanied by defect of the pectoralis major is said never to occur,<sup>2</sup> while only one case has been recorded where the condition has been bilateral.<sup>4</sup>

Heredity does not apparently play a very strong part in its production, since only once has the condition been noted in more than one member of a family—a case of father and two sons with this abnormality<sup>5</sup>—though other defects of development in the same family, such as accessory fingers or "webbed" toes, are occasionally met with. The pectoralis major is in some cases replaced by a fibrous band over which the skin becomes rolled, giving rise to a sickle-shaped fold which forms the anterior wall of the axilla.

Defects in the nipple and breast on the affected side are often present; both may be completely absent,<sup>6</sup> or the breast alone may be absent, with a rudimentary nipple, which is usually displaced upwards and inwards, as in the case described in this paper. There may also be a falling in of the chest on the affected side, due to defects in the cartilaginous portion of the second and third ribs; this portion may be markedly attenuated, or may be completely absent, its position being taken by a strong fibrous band.<sup>7-11</sup>

The amount of disability produced by the condition is, as a rule, extremely slight, as is seen by the case described by Burke<sup>12</sup> of a good left-handed baseball pitcher who had this abnormality on the left side, by the man recorded by Bruns<sup>13</sup> who was an expert turner, and by the student described by Stimizig<sup>14</sup> who was an excellent left-handed fencer, using his arm with the defect in preference to the other. In the case of the girl described in this article, with the abnormality on the right side, this arm was much stronger than the other, and she was able to throw a tennis ball twice as far with her right hand as with her left.

The most widely accepted view with regard to the origin of the condition is that advocated by Lewis,<sup>15</sup> who has shown that the pre-muscle mass from which the pectoral muscles are developed is situated in the lower cervical region in the early embryo and anterior to the first rib. As the embryo gets older the mass spreads out in the shape of a fan and moves downwards, becoming attached to the clavicle early and later to the ribs, sternum, and

abdominal fascia, while at the same time it becomes differentiated into major and minor muscles. He believes that the condition is due either to (1) failure of attachment and subsequent atrophy of the pectoralis minor and pars sterno-costalis of the pectoralis major; or to (2) lack of complete differentiation between the muscles. Probably both factors play a part in its production, but in favour of the latter view is the fact that there is always marked hypertrophy of the pars claviculæ when present in addition to hypertrophy of the deltoid.

The case here described was that of a girl, aged 13 years,

with absence of the pars sterno-costalis of the pectoralis major and the pectoralis minor on the right side. The condition is best demonstrated by getting her to put her arms straight forward and pressing her hands together. There is considerable hypertrophy of the clavicular portion of the pectoralis major and of the deltoid on that side. The muscle is not replaced by a definite fibrous band, the anterior axillary fold being formed by the clavicular part of the muscle. The breast on the right side is absent, and the ribs in that position are merely covered over with skin and subcutaneous tissue. The nipple is rudimentary, and is situated higher and nearer the middle line than on the other side. The ribs are normal, and x rays show no abnormality of the bony thorax; no scoliosis is present. There is no loss of power on the affected side owing to hypertrophy of the deltoid and clavicular part of the muscle.

It is of interest that she has also wasting of the left thigh and calf with some shortening—the result of an attack of acute anterior poliomyelitis when 2 years of age.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### THE VALUE OF ANATOMICAL DETAIL.

THE following case may be of interest as it serves to illustrate one of those finer details of anatomy which are apt to be forgotten and which sometimes assume considerable importance.

A married woman came to see me suffering from a wound on the dorsum of the right hand, a bowl having fallen from a height of about three feet on to her hand, splitting it open. The wound was comparatively clean cut, about one inch in length, and extended transversely across the extensor tendon of the middle finger, one inch from the metacarpophalangeal joint. On probing the wound it was found that the extensor tendon had been severed. In spite of this the patient could still extend the finger, although the movement was very slow and caused considerable pain. There was no apparent contraction of the extensor digitorum communis during the movement of extension. The patient was sent to hospital for treatment, but the diagnosis arrived at there was "extensor tendon half-cut." The treatment adopted was a skin stitch and finger splint. As I had informed the patient that the tendon was completely severed she naturally wished to have this little difference of opinion settled, and at her request I made an exploratory incision under local anaesthesia. I found the tendon completely severed, the proximal end having been drawn up the sheath for a distance of two inches. The sheath was opened and the tendon withdrawn in the usual way. The severed ends were then trimmed up and stitched together and the hand put up in a band and forearm splint in full extension.

Passive movement was commenced on the second day and active movement on the seventh. The splint was removed on the fourteenth day and the patient now has full use of her finger.

The point of interest lies in the fact that in spite of complete severance of the tendon the finger could still be fully extended.

The anatomical detail apt to be overlooked is that from the extensor tendon of the ring finger fibrous slips pass to the adjacent tendons. The slip going to the middle finger is inserted just proximal to the metacarpophalangeal joint. Before stitching the severed ends together the patient was asked to extend her fingers, and it could then be seen that it was this slip which was responsible for the function remaining. In addition, the insertions of the tendons of the lumbricals and interossei would also contribute in some degree to the movement of extension.

#### HUNTINGTON'S CHOREA.

WITH respect to the commentary by Dr. Grimby and Dr. Wilson on two cases of Huntington's chorea (*BRITISH MEDICAL JOURNAL*, May 8th and 15th, p. 820), and having regard to the pathology and rarity of the disease, I desire to record the cases of two patients who died within a day or two of each other in April last at the South Yorkshire Mental Hospital. One was a female and one a male, and

while the clinical symptoms were very similar and typical histories were obtained of several other members of the family having been insane and having chorea, yet the pathological pictures macroscopically were very different. The brain of the woman was small and firm, there was no thickening of the pia-arachnoid, the ventricles were only slightly dilated, the cerebro-spinal fluid was only slightly in excess, and there was apparently no wasting of the grey matter or basal ganglia; the brain of the man was large and very soft throughout; there was marked thickening of the pia-arachnoid, which was also adherent; the ventricles were very greatly dilated and the subarachnoid and ventricular fluid in great excess; there was marked frosting of the ependyma of the lateral and fourth ventricles. The grey matter and the corpus striatum were brown, very soft, and considerably atrophied, especially the caudate nucleus. In the brain of the woman the cerebral arteries were in good condition; in the brain of the man they showed numerous rings of sclerosis. Other details are as follows:

*Case 1.*—A woman, aged 41 on admission on June 22nd, 1921; no occupation. Several members of her family had been insane and had chorea, including her father and two uncles. She was imbecile and had previously been in mental hospitals for five years. She had delusions of persecution; the chorea was then only slight, but gradually became more severe, rendering her unable to do anything for herself and making her speech unintelligible. She died five years after admission.

*Case 2.*—A labourer, aged 52 on admission on November 25th, 1925. One brother and one sister had chorea and died insane. One brother had chorea and committed suicide; one brother is living but has chorea; one brother and one sister are living and healthy. The father had chorea and committed suicide. Two paternal uncles and a paternal grandmother had chorea and were insane. The patient had suffered from chorea for many years; he was imbecile and had latterly become irresponsible, mischievous, violent, and obscene; on admission he could give no account of himself, and the choreiform movements affected the whole body, including the face, and made the speech an unintelligible jargon. He died five months after admission.

In each case the terminal cause of death was a rapidly spreading inflammation, starting, in the case of the female, in an ischio-rectal abscess, and in the male in a boil of the gluteal region. As to the rarity of the disease during the last twenty years, I have been able to find mention of only two other cases at this hospital.

I am indebted to Dr. W. Vincent, medical superintendent, for permission to publish these cases.

FREDERICK BACK,  
Assistant Medical Officer and Pathologist,  
South Yorkshire Mental Hospital.

Sheffield.

### POISONING BY TOBACCO APPLIED TO THE SKIN.

THE case of tobacco poisoning following inunction, reported in the *JOURNAL* of April 24th (p. 739) by Drs. Jones and Morris, calls to mind a case that I saw in Italy in 1918.

Whilst "resting" in a small village behind the line I was asked one evening to see an Italian soldier lying sick in a farmhouse in which some of our men were billeted. I gathered that the man was home on short leave, and would have returned to his unit that day had he not been taken suddenly ill.

I found a young man lying in bed obviously ill, drowsy, flushed, and irritable. He complained of sore throat, headache, and diarrhoea. His temperature was 101° and the pulse over 100. The fauces, soft palate, and pharynx were all very red, but free from membrane. There was a generalized erythema on the trunk and limbs. No paresis was noted.

He was handed over at once to the nearest Italian military authorities, who, in reply to my request for a diagnosis, informed me that the case was one of tobacco poisoning, the method of administration being that usually adopted in this particular form of malingering.

The method was as follows: two *foscani* (cheap Italian cheroots of great potency, usually cut in half and smoked by the poorer classes), having stood some hours in a glass of water, were placed at bedtime one in each axilla and held in position by a puttee or bandage. In some cases, in order to make more certain of the effects, the man drank the water in which they had stood. The following morning he generally went sick, and so escaped duty.

Unlike the case reported by Drs. Jones and Morris, the nicotine had not been removed from the tobacco by combustion, and consequently it was the probable cause of the vasomotor upset.

## THE BLOOD VESSELS OF THE HUMAN SKIN.

AN ABSTRACT OF THE CROONIAN LECTURES, DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON,

BY

SIR THOMAS LEWIS, C.B.E., M.D., F.R.S.,  
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

THE Croonian course delivered before the Royal College of Physicians of London by Sir Thomas Lewis consisted of four lectures given on June 8th, 10th, 15th, and 17th. It dealt with work done in collaboration with Drs. Grant, Love, and Zotterman, and was intended to stimulate interest in the study of human physiology as opposed to animal physiology; the results considered refer to man only.

The description given by Spalteholz of the arrangement of the vessels in the skin was adopted as the anatomical basis for the observations.

The colour of the skin is mainly due to the blood contained in the superficial venous plexuses. The capillaries may contribute in small part to this colour, particularly in such regions as the palms of the hands and soles of the feet, as they are more numerous in these sites than in others. The contention of Spalteholz that all the blood to the skin passes through the capillaries in the papillae is in accordance with one of their functions—namely, the dissipation of heat.

The chief methods available for the study of these vessels are:

(1) Direct observation through the microscope as employed by Lombard. The skin at the base of the nail is very suitable for such observation. The capillaries here lie horizontally; the arterial loop is seen to be finer than the venous and the subpapillary venous plexus can be made out dimly; the blood flow and the red and white corpuscles can be distinguished. The capillary loops vary in size and in conformation in one field of vision and become larger as age advances. It is important to remember that the vessels visible in this way form only a limited proportion of the total and that they are all endothelial structures. The horny layer of the skin is an obstruction to the view, and after its removal by blistering the picture becomes much clearer; arteries can be seen to come up and divide and the capillaries to join the subpapillary venous plexus. Blistering, however, is not justified for physiological observations, since it alters the normal state; physiological observations are therefore confined chiefly to the tips of the capillary loops.

(2) Estimation of skin temperature by means of a specially constructed thermo-electric couple; alteration of the skin temperature indicates a corresponding alteration in the blood flow.

(3) Observations of skin colour, from which an estimate of the relative rates of blood flow can be made.

The reactions of the skin vessels to injury are of great importance and interest. Light and heavy stroking of the skin with a blunt instrument results in the appearance of the well known white and red lines respectively. The white line is due to the active contraction of the minute skin vessels—capillaries and venules—while the red line is but an element of a much more complex reaction. The development of the red line is accompanied by the appearance of a surrounding and brightly coloured irregular flush and is followed, if the injury has been sufficiently severe, or in a susceptible subject (urticaria factitia), by the formation of a wheal along the line of stroke. The red line itself is due to the active dilatation of the capillaries and venules, and also possibly of the terminal arterioles, and is independent of the nervous system. The surrounding flush is due to an independent and widespread dilatation of the arterioles brought about by a local axon reflex. The wheal is due to an outpouring of fluid from the vessels as a result of a local change in the permeability of the vessel walls, an increase of permeability which is independent of the dilatation and is uncontrolled by the nervous system.

The mechanism of this triple reaction to mechanical injury has been elucidated by studying the effect of the introduction of histamine into the skin. The physiological

properties of this substance have been worked out by Dale; it is found to be produced at the bowel, the lungs, and the liver, and is coming to be regarded as a normal metabolite. In the minute concentration of 1 in 30,000 histamine pricked into the skin produces the same triple reaction as mechanical injury. This evidence suggests that there is a fundamental and common cause at work, and it can be shown that this common factor is the presence of a diffusible substance in skin—histamine introduced on the one hand, and on the other a diffusible substance released in the skin by the mechanical injury and having a histamine-like action on the vessels and nerves. The evidence for this release of a diffusible substance by mechanical injury depends on showing that certain phenomena of the histamine reaction, which can only be interpreted as due to the presence of histamine in the skin, are exactly reproduced in the stroke reaction. Thus, for example, if the skin is stroked with the circulation arrested, the red line remains so long as the circulation is arrested and the local reaction is all the time increasing in breadth. If the circulation is not arrested then the red line fades slowly. Histamine produces identical phenomena, and in this case their meaning is clear—the histamine is diffusing out from the site of puncture. The clear correspondence of the course of events in the two cases is evidence that when the skin is stroked some diffusible substance is released. In similar manner it can be shown that the surrounding flush and formation of oedema in the stroke reaction also depend on this release of a diffusible substance in the skin.

This triple reaction, however, can be produced, not only by stroking and by the introduction of histamine, but also in a variety of other ways. It is produced by cold or freezing, by burning heat, the galvanic current, by ultra-violet light, by the application of such chemicals as hydrochloric acid, sodium hydrate, morphine, atropine, mustard oil, cantharidin, and many others. It is also produced by peptone and by antigen in those patients with hypersusceptibility to the protein concerned. Again, it is held that a common factor is at work; one property is common to all these stimuli—they produce tissue damage and by their action release a substance, identical in all cases, which sets in motion the mechanism of the triple reaction. At the moment it is not justifiable to say that this substance is histamine, but it is histamine-like.

These observations warrant the formulation of a more general law that every form of injury to the skin reaching a certain grade of severity calls forth a series of nervous and vascular reactions dependent on the same fundamental and natural chemical stimulus; in other words, there exists in the skin a single mechanism of defence against injuries of all kinds. Further, histamine pricked into the skin produces this triple reaction; introduced in greater quantity into the circulation it results in histamine shock. Slight injuries of all kinds produce this triple reaction; more severe injuries result in conditions closely akin to histamine shock—for example, wound shock and burn shock. There is a whole series of gradual transitions from the small daily injuries which pass almost unnoticed to the state of severe shock. The differences are quantitative, not qualitative; the defence mechanism, if excessive, is deleterious. It is another aspect of the conflict between the cell as an individual and the well-being of the body as a whole.

In the investigation of the action of heat and cold on the vessels of the skin numerous other points of interest arise, and special apparatus has been devised for applying these physical agents to the skin, and for registering the temperatures attained at the skin surface and subcutaneously. It is found, for example, that though the real freezing point of skin is probably very nearly that of normal saline ( $-0.6^{\circ}\text{C}.$ ) yet the highest temperature at which the skin has been frozen is  $-2.2^{\circ}\text{C}.$  and at this temperature it is not easily done; it is difficult enough at  $-10^{\circ}$  or  $-15^{\circ}\text{C}.$  At  $-20^{\circ}\text{C}.$  on some occasions freezing has not occurred—this is presumably the phenomenon of supercooling well known to physicists. Certain factors predispose to supercooling, chiefly the relative moistness of the skin and its content of grease. It is a factor of importance in considering why Arctic explorers may frequently be exposed to winds of  $-20^{\circ}$  or  $-30^{\circ}\text{C}.$

without invariably suffering frost-bite—the skin is naturally protected by supercooling, a protection enhanced by the grease which remains on the skin from lack of facilities for washing.

Finally, it has been shown that histamine punctured into the skin causes the production of a wheal, but if the circulation be arrested before the introduction of histamine and the arrest be maintained for fifteen minutes there is no whealing or only very slight whealing after the release of the circulation. If the circulation is released after only five minutes' occlusion whealing is full: the period of occlusion required for the prevention of whealing is shortened if the skin is warmed and prolonged if the skin is cooled. The failure to wheal is due to the loss of the increased permeability of the vessels first developed; it is not the result of the absence of histamine, as fresh histamine may be put into the spot which has failed to wheal after fifteen minutes' occlusion and still no wheal appears. To this phenomenon the term "refractoriness" has been applied. Refractoriness may be demonstrated, not only after the introduction of histamine, but in several other ways—for example, in the case of a patient who readily on stroking the skin. By

arresting the circulatory arrest the development of a wheal over the line of stroke may be prevented, though the red line develops, and, moreover, histamine punctured into this red line fails to produce a wheal. Again, if a wheal is produced by freezing or by ultra-violet light and allowed to subside, the damaged area is found to be refractory to stimulation in this sense. Recovery from refractoriness in these last cases is gradual, extending over days. The refractoriness refers to the phenomenon of permeability alone, but, in addition, the vessels in a refractory area have lost their power to contract, for example, to adrenaline and pituitrin; there is no evidence, however, that refractoriness and the unresponsiveness to adrenaline and pituitrin are the same phenomenon.

Refractoriness and unresponsiveness of the skin vessels to pituitrin and adrenaline are both found in a variety of clinical conditions. Thus, if the skin of the red reticulum seen in erythema *ab igne* be tested, the vessels fail entirely, or almost entirely, to react to histamine, and with adrenaline there is no blanching, or very little. The same phenomena are displayed by the vessels of the telangiectasis resulting from exposure to x rays, etc., of the port-wine stain, and of the skin of the faces of those who have long been exposed to the weather. As to the cause of refractoriness, no complete explanation is yet possible.

## Reports of Societies.

### HEALTH OF THE PROFESSIONAL WOMAN.

At a meeting of the London Association of the Medical Women's Federation, held on June 8th at the House of the British Medical Association, with Dr. CHRISTINE MURRELL, President, in the chair, Dr. LETITIA FAIRFIELD gave an address on the health of the professional woman.

Dr. Fairfield said that excessive sickness among women compared with men was a recognized feature of all statistical tables; especially between the ages of 45 and 65 the female morbidity rate was much higher than the male rate, though the female death rate was lower. This excess of sickness gave some grounds for differences in pay where work was equal, and it was therefore important to analyse its causes. The health of professional women was less easy to investigate than that of the working classes, but in the speaker's work for the London County Council she had been able to survey a wide range of cases and to make some interesting comparisons between men and women of the teaching profession. The rules of the L.C.C. were that every teacher away for more than three days had to have a certificate from her own doctor. If the absence lasted more than a month the case was referred to a Council medical officer, and the teacher was asked to see the medical officer with reference to sick leave. In cases of absence due to debility, headache, or neurosis action was taken after more than three days' absence. Dr. Fairfield's

aper dealt with 900 cases, of which nervous cases formed large proportion; pulmonary conditions also figured largely. Recurrent bronchitis among elderly teachers accounted for many of the absences, but phthisis was rare. The cardiac after-effects of influenza she had found very severe, and rheumatism affected more women than men teachers. In the indigestion group appendicitis accounted for many cases. The improvement in the condition of the youth and teeth of teachers during the last ten years was most remarkable. Out of 900 cases there were only 12 in whom untreated pyorrhoea was even a probable cause of ill health, and only in 2 was dental treatment resisted. In Dr. Fairfield's opinion the most urgent health measure needed in the country was increase in facilities for dental treatment of the whole nation. As to constipation, it was curious that those who suffered from constipation were nearly all large fruit-eaters; it seemed to her that among many town dwellers the consumption of vegetables was decreasing while that of fruit was increasing, and that the change was not advantageous from the point of view of intestinal stasis. Mild enteroptosis was often to be seen where the diet did not appear to be faulty, but the improvement in physical training of girls was doing much to combat this abdominal flabbiness. The chronic dyspeptic cases seemed to be diminishing. As to diseases which might be termed "occupation diseases," laryngitis with no obvious lesion was common among teachers; excision of tonsils in quite elderly people might help this condition. Exophthalmic goitre, although not common, was very serious when it occurred among teachers; teaching could seem to be the worst kind of occupation for sufferers from this condition. They should be advised to seek other occupations, since they were ill suited to cope with children. A group of cases in which a large discrepancy between men and women was apparent on the surface was that of anaemia and debility. The evidence of medical certificates would suggest that it was three times as common among women, but when these cases were carefully investigated the typical signs of anaemia appeared to be absent, and it was probable that this term was used loosely in giving certificates for short absences. As to the diseases peculiar to women, in Dr. Fairfield's experience the phobia of the menopause was much more serious than the menopause itself. Only 11 cases of ill health among the 900 cases were found on investigation to be really due to the menopause, though many cases were attributed to it, in one instance over a period of eight years. Functional nervous disease was commoner in women than in men, the proportion being 4 to 3. The severity of an alleged cause for functional nervous disease appeared to be in inverse ratio to the severity of the disease. In her opinion the general practitioner should treat these cases, being in a position to know the circumstances and surroundings of the patient.

Dr. ELEANOR LOWRY suggested that the occupational laryngitis might be caused by bad voice production, sinus trouble, or excessive smoking. Dr. JUSTINA WILSON, from her experience at the National Hospital for Diseases of the Heart, confirmed the much greater incidence of rheumatic heart disease in women. Heart disease following influenza appeared to be very deadly to the heart muscle. Dr. MARY KIDD agreed that vegetables rather than fruit were needed to prevent constipation. It was unfortunate that vegetables were so expensive nowadays, and also that considerable time had to be spent in cleaning and cooking them, which the woman worker living alone could ill afford. Dr. RUTH VERNER deplored the lack of cheap institutions for cases of functional nervous disease, since many such patients could only be treated away from the home circumstances which had contributed to the breakdown. Dr. MINA DOBBIE said that practitioners ought to inquire how working women spent their leisure and holidays. Often it was found that they looked after aged relatives from a sense of duty, and were quite grateful to practitioners who forbade them to do so. Dr. ROBERTS suggested that a possible cause of neurosis in elderly teachers was a sense of failure in not having advanced further in their profession and a lack of anything to look forward to. Dr. PEAKE pointed out that the effects of the menopause might not be immediate—for example, flushings could occur long after

the actual cessation of menstruation. Dr. A. SHEPPARD pointed out that in some banks the compulsory retiring age for women was as early as 45. The PRESIDENT pointed out that the other duties outside work performed by most professional women would account for some of the excess of functional nervous disease. Neurasthenia, in her opinion, was always the result of emotional overstrain. There was a need for well run nursing homes in psychological institutions where the practitioner could continue to treat the patient.

## Reviews.

### PANEL PRACTICE.

THE author of this small book, *On the Panel: General Practice as a Career*,<sup>1</sup> is a panel doctor who, for obvious reasons, prefers to remain anonymous, and who, we are told, is a country practitioner with a panel list of about 2,500 insured persons and a private practice worked by himself and a partner. The early part of the book deals with the general management of a panel practice. A typical day's work of a country panel practitioner is described in detail, including surgery attendances and visits, and many common-sense hints are given on how to manage patients so as to gain their confidence. Great stress is laid on the necessity for careful examination and the desirability of obtaining a second opinion whenever there is doubt about diagnosis; in this connexion the author states that he often finds himself at a loss owing to the absence of any provision for free consultant advice. He is evidently one of the great number of insurance practitioners who treat their panel patients as conscientiously and as carefully as their private patients. He finds that 2,500 panel patients in addition to private patients are as many as he and his partner can attend to properly, and adds that he "does not advise anyone to go in for panel practice unless he has really good health." In common with most insurance practitioners, he often finds difficulty in the giving of certificates of incapacity, and laments the absence of an authoritative definition of "fitness for work" and "fitness for light work only." The Ministry of Health memorandum on the term "incapable of work," which is quoted in full, was not, he thinks, written with sufficient care.

It is clear throughout the book that the author has formed a high opinion of the advantages conferred on the working classes by national insurance, the chief being the facility for obtaining medical treatment whenever required; the uninsured population, apart from the wealthy classes, suffer enormously, he considers, through their inability to pay for medical attendance. He strongly advises the extension of medical benefit to the wives and children of the insured. Under medical benefit he would also include consultant and specialist treatment and hospital treatment; he calculates, however, that the cost would be almost prohibitive, and suggests that the approved societies might pay part and the patients the rest. The difficulties in the way of this are not overlooked, and there is something to be said in favour of the suggestion for cottage hospitals, where needed, at which general practitioners, including those on the panel, may become proficient in various specialisms. Here again the question of cost arises, and with the extension of the benefits to nearly three times the number of the present insured the increased demand for the services of the doctors, already overworked, can, he thinks, only be surmounted when preventive medicine has materially reduced the general sickness rate. A great part of the book is taken up with the discussion of questions like these, which are perhaps as much political as medical.

The book can be recommended as a practical guide, full of homely advice, for medical men commencing general, and especially panel, practice, while those parts that deal with the scope of national health insurance are evidently the outcome of personal experience and deserving of careful consideration.

<sup>1</sup> *On the Panel: General Practice as a Career*. By a Panel Doctor. With a Foreword by Dr. C. M. Wilson. London: Faber and Gwyer, Ltd. 1925. (Cr. 8vo, pp. viii + 294 6s. net.)

## THE THYROID GLAND.

THE Beaumont Foundation Lectureship Committee of the Wayne County Medical Society has been fortunate in securing two such authorities as CHARLES H. MAYO and H. W. PLUMMER to lecture on *The Thyroid Gland*,<sup>2</sup> for at the Mayo Clinic during the period 1892-1925 there have been 14,505 cases of adenomatous goitre and 8,223 of exophthalmic goitre, and during the year 1924 the total number of cases of goitre, simple and exophthalmic, submitted to operation was 1,785, with a mortality of 10, or 0.58 per cent. Of the two parts of this pamphlet, which is rather highly priced, the first, of a general introductory character, dealing with the anatomy and physiology of the thyroid, the etiology and distribution of goitre, the metabolism in exophthalmic goitre, and a few pages on the parathyroids, is by Dr. Charles Mayo. In the second part, headed "The function of the thyroid," Professor Plummer states that this is to maintain 14 mg. of thyroxine in the body, or to elaborate 0.33 mg. of thyroxine daily; he classifies goitre as exophthalmic and as endemic, the latter being divided into diffuse colloid and adenomatous, and the adenomatous again into those with and those without hyperfunction. The view expressed is that the most essential factor in the etiology of endemic goitre is a relative or absolute deficiency in iodine; this leads to hypothyroidism in the first instance, and then stimulation of the thyroid produces diffuse hypertrophy and colloid is stored in excess.

It is maintained that in many cases continued stimulation of the thyroid combined with unknown factors results in adenomatous formation, and that relatively late in the history of the thyroid changes this adenomatous tissue becomes excessively active. Of adenomatous goitres removed from patients under 30 years of age 5 per cent. were functionally overactive, while, in patients over 60, 60 per cent. were in this state. Colloid goitres, it is stated, can be rapidly diminished when thyroid is administered; Professor Plummer believes that when given to patients with adenomatous goitre iodine may initiate hyperthyroidism. In considering the relation between the two, the manifestations of an excessively functionally active adenoma are said to be reducible to physiological terms, whereas those of exophthalmic goitre cannot. In 1912 Plummer suggested that in hyperfunctioning adenomatous thyroids (toxic goitre) there is merely an excess of thyroid secretion, whereas in exophthalmic goitre there is in addition an abnormal secretion with a special affinity for nervous tissues; later he thought that there might be a third toxic agent causing exophthalmos and ocular symptoms. Remarkable and rapidly beneficial results obtained by administration of Lugol's solution in exophthalmic goitre are described, and the appropriate dose discussed. The operative mortality of exophthalmic goitre was reduced by the Lugol treatment from 3.5 to 1 per cent. For these reasons alone it is worth while for every practitioner to read this compact lecture.

## PLASTIC SURGERY OF THE NOSE.

At a time when plastic surgery is making such rapid advances and the literature of the subject is becoming more and more extensive, *Plastic Surgery of the Nose*,<sup>3</sup> by Dr. J. EASTMAN SHEEHAN of New York, is welcome in that it represents an attempt to treat in detail a single branch of the work.

The introduction, which is excellent, contains arguments for the recognition of procedures for the repair of nasal disfigurements as belonging to dignified surgical practice, and emphasizes the necessity for specialization in this delicate type of surgical work. We cannot accept the opinion that an external central columellar incision is the best for practically all plastic procedures on the nose. Most patients object—quite justifiably—to a nasal opera-

tion which leaves any external scar, and it is not encouraging to be informed that "even a bad scar, so placed, can readily be eliminated." The edges of such an incision—necessarily limited in length—are very liable to be damaged by the extensive manipulations carried out through it; the scar is frequently bad, and even a good columellar scar is usually very visible. Stress is laid on the disastrous results of paraffin injection for contour correction. Cartilage is advocated in preference to bone or artificial material for the restoration of the nasal bridge: the arguments in its favour are well known.

A useful chapter describing the anatomy of the nose is followed by an exhaustive list of the conditions for which surgical intervention may be indicated. Preparation of the patient is dealt with in considerable detail; the strenuous local treatment advocated seems to us excessive, for by irritating the delicate lining of the nose it is likely to defeat its own object. Reduction of a hump-nose is taken as a typical operation for description. The hairpin retractors and the angulated knife used are worthy of note. Special methods of bandaging and various means of minimizing oedema and bruising are discussed at length. Infection is mentioned, and it is admitted that the columellar incision may require opening for drainage purposes. The advantages of an intranasal incision in such a contingency are here again made obvious. It is better to dispense with the special pads and bandages recommended for maintaining correction after operations undertaken for straightening the crooked nose. If the operation has been sufficiently radical any tendency to displacement of the corrected bridge line can be readily corrected by painless digital manipulation from day to day as the bones are resetting; external appliances are very liable to become deranged and to maintain rather than correct displacement. It is difficult to understand how small sections of the lateral cartilages of the nose are removed with the precision described when the incision is made so far away from them. For depression of the nasal bridge a hinged cartilage graft—well known in this country as the Gillies method—is advocated. Dr. Sheehan recommends fixation of the columellar portion of the graft by a catgut suture.

The instructions for dealing with a variety of conditions ranging from "protrusion of the septum" to "twisted tip" are rather scanty and indefinite; operations on these deformities are among the most difficult of all plastic procedures. Such sentences as "The mesial crus is partially excised towards its middle, and excisions are made from the lateral crus if the conditions and the plan of repair call for such excision" do not guide the operator very far. The usual type of submucous resection for deflected septum is described—but why should it be made through the external columellar incision when the usual intranasal route gives such excellent access and results? In the chapter on deformities of the alae the instructions are again scanty and difficult to follow, but an ingenious method of cartilage grafting of the maxillae for the correction of "dish-face" is well worthy of note.

Rhinophyma, paraffinoma, recent injuries, the syphilitic nose, various methods of rhinoplasty, methods of skin grafting, forms of skin flap, and "occasional disfigurements" are fully dealt with. The necessity for and the means of supplying lost lining in dealing with syphilitic affections of the nose are discussed, and acknowledgement is made of the pioneer work of Gillies on this subject. In planning flaps for complete rhinoplasty the author appears to be a little optimistic about the depth of hair-free skin available on the average forehead, for it is difficult to understand how the flaps pictured as taken from the central portion of the forehead in a vertical direction manage, when turned down, to reach the tip of the new nose and, in some cases, even to form a new columella. The appendix on anaesthesia overlooks the chief advantage of the two-tube form of intratracheal anaesthesia (introduced into this country by Magill) which lies in the ability to pack off the pharynx completely without interfering with either the inspiratory or expiratory airway.

The volume is well printed and beautifully and lavishly illustrated.

<sup>3</sup> *Plastic Surgery of the Nose*. By J. Eastman Sheehan, M.D., F.A.C.S. With a Foreword by John F. Erdmann, M.D., F.A.C.S. New York: P. B. Hoeber, Inc. 1925. (8 x 10½, pp. xix + 249; 177 figures. 10 dollars net.)

## TUBERCULOSIS IN GERMANY.

The first of two volumes of a handbook<sup>4</sup> on the care of the tuberculous has reached us. It is a collection of articles by different authors on the tuberculosis problem, edited by Dr. KARL H. BÜMEL of Halle. Ranging over a wide field, its keynote is the administration and organization of treatment centres. More than a hundred pages are devoted to the legal aspects of the disease, to the duty of the doctor to his patient and the State, to the punishments that await his folly or recalcitrance, and to the question of notification.

One of the most valuable contributions is the chapter on statistics. Unfortunately, owing to the lack of compulsory notification of tuberculosis in Germany, these are confined to the mortality figures, but in these alone and in their comparison with the figures of other nations is to be found most interesting matter for reflection. During the war the deaths from all forms of tuberculosis rose considerably, reaching their highest point in 1918, when 2.3 deaths per 1,000 living occurred. In 1921 the mortality rate had fallen to 1.37 per 1,000, but during the following years it rose slightly. These figures must be considered in relation to the change in the distribution of the numbers in the different age groups. Thus the proportion of children in the 0-5 age group in 1919 was under half that in 1910, whereas the proportion of the population in the age groups between 30 and 70 had risen considerably. It is interesting to note that there is no relation between the tuberculosis mortality and the total mortality from all causes; that in many States the mortality amongst females is higher than amongst males; that the mortality in the large towns is less than in the towns of medium size, and that in 1921 9.4 per cent. of all deaths amongst males and 10.2 per cent. amongst females were due to tuberculosis.

The latter part of this volume deals chiefly with occupational tuberculosis, tuberculosis in children, and differential diagnosis. The book is full of information, and should appeal to historians, medical statisticians, and clinicians alike.

## GALLIPOLI.

A FEW years ago someone said of Gallipoli that it would go down to history as a disgrace to British statesmanship and British strategy; and the late Walter H. Page described it as "a horrible tragedy, where the best soldiers in the world were sacrificed to politicians' policies."

Sir GERALD ELLISON, in his *Perils of Amateur Strategy*,<sup>5</sup> exposes the circumstances which led to so trenchant an indictment of what, apart from politics and strategy, brought out, at the expense of thousands of lives and infinite suffering, the finest and most heroic qualities of the fighting forces of the British Empire.

The amateur strategy which he attacks was the decision of the Cabinet, at the instigation of the then First Lord of the Admiralty, to undertake an expedition against the Dardanelles fortress, an undertaking which naval and military experts had previously regarded as bound to fail. There is a prefatory note by Lord Esher, but it should be read after and not before the rest of the book. He disagrees with General Ellison's main argument, but accepts his conclusions. He defends Mr. Churchill against the accusation of being an amateur strategist. It is difficult, however, after reading what General Ellison has to say, to avoid the feeling that the whole conception and launching of the expedition, with its lack of secrecy and, consequently, of the element of surprise, savours strongly of amateur strategy.

The principle that strategy begins where politics ends has been laid down by the authorities on war from time immemorial; and it was this principle which was ignored. Mr. Churchill's own words illustrate this. In his book *The World Crisis* he writes that "the distinction between

politics and strategy diminishes as the point of view is raised. At the summit true politics and strategy are one." General Ellison's comments on this are: "ergo, quite obviously, the politician is fully qualified to deal with strategy. Hence amateur strategy! Hence Gallipoli!" These words express in a nutshell what he endeavours to expose in the pages of his book.

Within three months of war being declared, a War Council, of which the Chief of the Imperial General Staff was not a member, eclipsed and swept away the original conception of a General Staff. We are told that the system, by which politicians have the power to interfere with strategy, still exists and may lead to disasters similar to that of Gallipoli unless a new system of strategical control is adopted. General Ellison's proposal is that the Committee of Imperial Defence should have two distinct sections—a policy section and an operations section, the latter formed of the chiefs of the staff of the three fighting services.

If such a solution, for avoiding the perils of amateur strategy, is realized, it is to be hoped that due regard will be paid in the operations section to the medical aspects of a campaign; for neglect of these may prove as perilous to the nation as amateur strategy. There was at one time a medical section in the directorate of military operations; and history records how valuable it was in connexion with preparation for war between 1906 and 1914. We may ask why it has not been resuscitated since the war.

There is much food for thought in General Ellison's book. It will no doubt arouse a considerable amount of criticism and controversy, which the medical services will follow with interest. What they desire most, and would welcome whole-heartedly, is that due consideration should be given to the medical aspects of a campaign in determining its strategy.

## NOTES ON BOOKS.

MR. BORRADAILE'S *Manual of Elementary Zoology* has now reached its fifth edition,<sup>6</sup> and considerable parts of the introductory chapter and of those dealing with reproduction and sex, and the relation of animals to the world, have been rewritten. We reviewed the third edition on October 30th, 1920 (p. 668), and it only remains to call attention to the comprehensiveness of a very valuable book which aims at providing information for medical students.

The volume of *Collected Papers by the Staff of the Henry Ford Hospital*<sup>7</sup> in Detroit, Michigan, represents the scientific writings by the members of the hospital staff since its foundation in 1915 down to the end of September, 1925; the majority of the papers have appeared during the past two years. One appendix is devoted to a short account of the history and equipment of the hospital, and articles dealing with technical appliances are grouped in a second appendix.

"Les Petits Précis"<sup>8</sup> is a series of small books edited by Dr. A. CANTONNET, the object of which is to supply the French medical student and practitioner with the indispensable minimum of knowledge in each specialty in medicine. Thus in Dr. Paul Halbron's book on infectious diseases in fewer than two hundred pages an up-to-date but inevitably fragmentary account is given of thirty-two diseases, including not only the common acute infectious diseases prevalent in Europe but also plague, cholera, dengue, sleeping sickness, and papataci fever. A list of the diseases notifiable in France is appended. Other volumes of the series of fifty-four which have reached us are *Tuberculoses ostéo-articulaires et ganglionnaires*, by Drs. E. SORREL and A. DELAHAYE; *Grossesse et Accouchement Pathologiques*, by Dr. J. LÉZELAND; *La chirurgie infantile*, by Dr. A. MARTIN; *Le Cancer*, by Dr. G. JEANNENEY; *Oto-rhino-laryngologie*, by Dr. L. BALDENWECK; *Rayons x et corps radio-actifs*, by Dr. A. LAQUERRIÈRE; *Examens de laboratoire*, by Dr. A. BEAUVY; and *Dermatologie du Praticien*, by Drs. G. LACAPÈRE and H. MONTAUD. The books are of handy size, small and light, so that it is easy to carry one about in the pocket for

<sup>4</sup> *Handbuch der Tuberkulose-Fürsorge*. Erster Band. Herausgegeben von Dr. Karl Heinz Bümel. München: J. F. Lehmann, 1925. (Roy. 8vo, pp. viii + 457; 46 figures on plates, 61 figures in the text. M.24; bound, M.27.)

<sup>5</sup> *The Perils of Amateur Strategy, as exemplified by the attack on the Dardanelles Fortress in 1915*. By Lieut.-General Sir Gerald Ellison, K.C.B., K.C.M.G. London: Longmans, Green and Co., Ltd. 1925. (Cr. 8vo, pp. xxvi + 152; 2 maps. 5s. net.)

<sup>6</sup> *A Manual of Elementary Zoology*. By L. A. Borradaile, Sc.D. Fifth edition. Oxford Medical Publications. London: H. Milford, Oxford University Press, 1925. (Cr. 8vo, pp. xvi + 670; 468 figures. 15s. net.)

<sup>7</sup> *Collected Papers by the Staff of the Henry Ford Hospital*. First series, 1915-25. New York: P. B. Hoeber, Inc. 1925. (Med. 8vo, pp. xxi + 63; illustrated. 8 dollars net.)

<sup>8</sup> "Les Petits Précis." Bibliothèque dirigée par A. Cantonnet. Paris: A. Maloine et Fils. 1925 and 1926. (42 x 61; illustrated. 8.50 fr. each volume.)

## PREVENTION OF TUBERCULOSIS.

NATIONAL ASSOCIATION FOR THE PREVENTION  
OF TUBERCULOSIS.

THE twelfth annual conference of the National Association for the Prevention of Tuberculosis was held in Glasgow on July 1st, 2nd, and 3rd. The Hon. Sir ARTHUR STANLEY, G.B.E., presided at the various sessions of the conference. The delegates were welcomed by the Right Hon. Lord Provost Sir MATTHEW W. MONTGOMERY, LL.D., who spoke of the valuable and beneficent work which had already been done by the association.

## Non-pulmonary Tuberculosis.

At the first session of the conference on July 1st, a discussion on the provision for the care of non-pulmonary tuberculosis was opened by Dr. A. S. M. MacGregor, medical officer of health for the city of Glasgow, and Mr. JAMES TAYLOR, consulting surgeon of the Glasgow Corporation hospitals and sanatoriums. Dr. MacGregor said that the field for the treatment of non-pulmonary forms of tuberculosis was as yet only partially covered, and the principal question at the present time was the form the facilities for treatment should take. A serious result of delayed treatment was the destruction of bone, which led to crippling and deformity. The excellence of the results obtained were impaired by the late arrival of patients in the institutions provided for treatment. Mr. James Taylor expressed the belief that the improvement of housing conditions and the provision of plenty of air and sunlight for the people as a whole, although it might entail great initial expenditure, would go a long way towards cutting down the sums that were yearly spent on the maintenance of tuberculosis hospitals. Dr. J. G. JOHNSTONE, medical superintendent of the Heatherwood Hospital, Ascot, quoted statistics to show that there was not sufficient bed accommodation or sufficient after-care organization throughout the country for treating non-pulmonary cases of tuberculosis, compared with the pulmonary type, was eminently arrestable. The records of most special hospitals dealing with these cases showed that 80 or 90 per cent. could be arrested. He had found, however, that only about 45 per cent. of cases applied for treatment at the hospital within one year of the appearance of the disease, while the remainder had suffered for a long period, some of them for as much as seven or eight years. He was not to be taken as asserting that these patients had been totally without treatment during these years; as a rule, they had had some kind of treatment in a general hospital or at a tuberculosis dispensary, but their state on admission to hospital with the disease far advanced, and crippling deformities developed, was not at all satisfactory. The fact, too, that the surgeon, who treated in hospital a patient coming from a remote district, could not know the result did not make for progress in the treatment of the disease. After-care in such cases had to be continued for several years after in-patient treatment, but the shorter the period for which the disease had already lasted, the shorter also would be the period of treatment, and the better the end-result. Another aspect of the problem was the financial one. It was found that the average cost of arresting the disease in cases discharged from hospital was: for the spine £262, for the hip £309, and for the knee £198. It was hoped in the near future to institute, in connexion with the Heatherwood Hospital, a series of clinics in the metropolitan area and some of the home counties areas, and he thought this was an object deserving of the fullest sympathy and earnest endeavour. The Central Committee for the Care of Cripples had formulated a national scheme whereby each authority or group of authorities should institute a central hospital and a system of clinics in the outlying districts. Such hospitals should be staffed with a competent orthopaedic surgeon, trained sisters, and nurses specially trained in after-care methods. It was advisable also to effect a liaison with a general hospital, as it was often desirable to obtain the advice of members of other branches of the profession. Dr. J. H. PAUL (Millport) described in detail the work of a voluntary institution at Millport in Buteshire, which had proved that real open-air treatment was possible in winter as well as in

refreshing one's memory in a particular specialty. But the condensed style in which each subject is treated is not conducive to pleasure in reading. In several volumes there are quite good illustrations, some rather comic, as in the cave-man drawing of the head of a person undergoing anterior rhinoscopy.

It demands a measure of courage amounting almost to temerity to write verse for children. There are two reasons: First, in the matter of substance, it is extremely difficult for even the most patient and sympathetic of us to find out what and how a child is thinking, and we have all of us forgotten. Secondly, in the matter of form such a title as *Child Verses and Poems*<sup>9</sup> compels comparison with Robert Louis Stevenson's *The Child's Garden of Verses*, a little masterpiece in form and substance. The medical writer who has just put out under a pseudonym the small volume, whose full title is quoted above, has the necessary sympathy, and sometimes the necessary simplicity, but sometimes spoils all by long words, though we will admit that "peppermint-drop" is not a really truly long word; it comes at the end of four stanzas on three gnomes, and was a suitable reward for their daring. In another piece are two happy couplets describing the disconcerting stare with which a young child examines a new acquaintance; they may be quoted as an example of the author at his best:

"Some think because so long I stare  
I keep no thoughts behind my hair,  
But smile I will not as I should  
Unless I find them bright and good."

The drawings by Cecile Walton are also good. The book contains some other poems, and we commend it to all child lovers.

*Caravanning*,<sup>10</sup> by J. HARRIS STONE, with its numerous attractive illustrations and beguiling narrative, will tempt many a reader, hitherto a stranger to this form of recreation, to consider whether the present vogue of gathering in groups in fashionable resorts cannot be profitably replaced by a more romantic and healthy activity. The author's description of caravan life is full of practical detail; useful hints are given for almost all conceivable emergencies, and the restful leisure of a holiday spent in this way is very clearly indicated. The variety of caravans available is such as to meet all tastes and pockets.

*The British Goat Society's Year Book for 1926*<sup>11</sup> is the sixth issue of a popular and useful annual. A short account is given of the second International Goat Congress in Switzerland last September, when seventy delegates from ten different countries were present. A tabulated statement of the yield of milk of all the goat herds for the two previous years is reprinted by permission of the Minister of Agriculture and Fisheries and the Central Council for Milk Recording Societies; it indicates the steady extension of this industry in Great Britain. As in previous numbers of the *Year Book*, there is to be found in this issue a large variety of articles dealing with many aspects of practical goat-keeping and research in goat-breeding. The numerous illustrations are a pleasing feature of the volume, the practical value of which will commend it to all interested in goat-keeping.

<sup>9</sup> *Child Verses and Poems*. By Austin Priestman. Illustrated by Cecile Walton. London: A. H. Stockwell, Ltd. 1926. (Cr. 8vo, pp. 96; illustrated. 4s. net.)

<sup>10</sup> *Caravanning*. By J. Harris Stone, M.A. Cantab., F.L.S., F.C.S. Third edition. London: The Caravan Club of Great Britain and Ireland. 1926. (Demy 8vo, pp. 45; illustrated. 6d.; post free 7d.)

<sup>11</sup> *The British Goat Society's Year Book for 1926*. London: T. W. Palmer, 10, Lloyd's Avenue, E.C.3. (Demy 8vo, pp. 163; illustrated. 1s. 6d.)

PREPARATIONS AND APPLIANCES.  
Vitrocol Spatula.

VITROCOL is the name given to pure silica fused by an electric process in the works of the Thermal Syndicate, Ltd. The substance possesses great resistance to acids and heat, so great that it can be used, for working purposes, up to 1,100° C. or higher, and it is unaffected by any acids except hydrofluoric, also, at a high temperature phosphoric. At high temperatures, also, caustic alkalis and certain metallic oxides affect it. Dr. J. Barker Smith (Herne Hill) has designed a small spatula of this material for the char test, for detecting sugar in urine, blood, tears, and other secretions (BRITISH MEDICAL JOURNAL, March 27th, 1926, p. 602). It is said that when the droplet of urine is evaporated, charred to a cinder, and the silica disc plunged into water, rubbing with the finger-tip will leave a residue or "phantom char" when sugar is present. The procedure is also accompanied by an odour of caramel.

summer, even in Scotland. Dr. W. B. KNOBEL, divisional medical officer, London County Council, said that in London no child was kept waiting a single day for treatment of surgical tuberculosis, but the County Council had difficulty in getting cases at an early stage. Professor Sir ROBERT PHILLIP said that this form of the disease was not confined to the poor; non-pulmonary tuberculosis prevailed all over the world among the high and the low, and many of the richest and noblest families had been afflicted by it. The nature of the disease made treatment difficult.

#### *The Tuberculosis Dispensary.*

At the afternoon session, "The actual place and function of the tuberculosis dispensary in the tuberculosis scheme" was treated in a paper by Sir ROBERT PHILLIP, which is given in full at page 55 of this issue. Dr. LISSANT COX, central tuberculosis officer, Lancashire County Council, who followed, said that the tuberculosis dispensary system, which was to-day in operation, was a distinctive feature of British work, and was carried out by 350 tuberculosis officers; it earned unstinted foreign praise wherever the matter was studied. In the larger administrative areas the tuberculosis officer ought to be a specialist doing this work alone, and should not be employed on other public health work. The same thing might be achieved in the smaller areas if they would combine to provide a whole-time tuberculosis officer. It was necessary that each consultant tuberculosis officer should have a small laboratory at the chief dispensary for the area, with a trained laboratory worker attached; the officer should have his own x-ray apparatus and take his own skiagrams; this would enable him to follow his patients throughout their illness, and to build up his knowledge of x-ray appearances, so that he could correct and modify his opinions in the light of the development of the cases. While x-ray examinations should not take the place of other methods, they rendered the facilities for diagnosis better. In the past too much emphasis had been laid on treatment rather than on prevention, which was the real and ultimate goal. Much should be done by the dispensary in obtaining better notification of cases, and so reducing the chances of infection. Much also could be done by education, especially through the dispensary nurses; as the result of dispensary work in Lancashire the number of persons per 100,000 dying from consumption had fallen from 107 in 1918 to 67 in 1925. Dr. W. B. KNOBEL said that an important question was whether, under the dispensary organization, the greatest number of cases possible was being detected in the early stages of the disease. In spite of many years of working and propaganda, three-quarters of the cases were in a more or less advanced stage of the disease when they first came under these schemes. This was so serious a criticism that he considered it was a question whether the dispensaries were organized on the right lines, and he suggested that it was desirable that more reasonable propaganda, distinguishing between infective and non-infective cases, should be before the public. Dr. WILLIAM BRAND (Camberwell) said that there was a cry from the sanatoriums to give them early cases, and those who were in charge of the centres of diagnosis in the dispensaries must comply with this. With the full co-operation of the general practitioner in a district, the diagnosis of contacts might be greatly simplified. The dispensaries should not, however, attempt too much; their main function was the organization and supervision of home treatment of tuberculosis in each area. Dr. J. MCCALLUM LANG (Lanark) said that a classification of dispensary patients according to age and sex was of interest in assessing the value of dispensaries as a means of detecting tuberculous disease in its early stages. In the middle ward of Lanarkshire, with a population of 237,000 persons, mainly industrial but partly agricultural, 65 per cent. of the tuberculous cases were children under 15 years of age. More adolescents must be induced to present themselves at the dispensaries if the primary duty of procuring a diagnosis in the earliest detectable stages was to be accomplished. There was no age at which vaguely suspicious symptoms demanded more careful consideration than between 15 and 25 years. The dispensary played a valuable part also as a "clearing-house"; for, of all the patients who presented

themselves for examination, only 44 per cent. were found to be tuberculous. The dispensary thus prevented the over-notification of tuberculosis, for he considered that in areas with no dispensary facilities many suspects were formally but wrongly notified as cases of tuberculosis. The educative function of the dispensary should also be kept well in view. The dispensary had, too, its part to play in the examination of contacts, but it should be remembered that this function was also discharged by the school medical service and by the national health insurance system.

#### *Experimental Studies in Tuberculosis.*

At the morning session on July 2nd a paper on experimental studies in tuberculosis with reference to the origin of pulmonary tuberculosis was read by Dr. C. H. BROWNING, professor of bacteriology in Glasgow University. The problem of pulmonary tuberculosis, he said, was the essential problem of tuberculosis in the adult. It must not be imagined that whenever the tubercle bacillus reached an individual the result was tuberculosis, for the chances were that in most cases nothing, or at least very little, would happen to the human host. The credit for throwing doubt on the early doctrine that inhalation was the sole cause of pulmonary tuberculosis belonged to the Norwegian physician Andrvord. Though tuberculosis might be acquired by inhalation of infected material, it was by no means certain that it was the only method by which tuberculosis of the lungs arose. Tuberculosis in European countries might be described as an endemic disease—that was to say, it was continually smouldering; and it might be considered that the relatively chronic form in which pulmonary tuberculosis existed in the adult was probably to be attributed in great part to this smouldering fire of tuberculosis. Referring to laboratory experiments on mice, Professor Browning said that this animal was very suitable for investigation because, like the European population, it was relatively resistant and might go on for a year or two after tuberculosis infection had been imparted to it. Out of some 300 mice inoculated by way of the abdominal cavity, 7 or 8 per cent. showed at death massive pulmonary lesions due to tubercle bacilli and nothing else. In a feeding experiment the result was also very striking, for in 11 out of 20 animals which had received tubercle bacilli with their food pulmonary lesions of large size were the only evidences of tuberculous disease. There thus appeared to be an affinity between the tubercle bacillus and the lung, and it appeared from these experiments that the tubercle bacillus might reach the lung by other routes, leaving little or no trace of the path which it had pursued in entering the body. It must, therefore, be assumed that the origin of lung tuberculosis was to be summed up in the word "inhalation." In the present state of knowledge administrative measures devoted to the prevention of pulmonary tuberculosis must not be stereotyped, since it was not possible to say which of the various factors played the largest part in the production of the disease.

#### *Treatment by Artificial Sunlight.*

Dr. ALEXANDER SMITH (Robroyston Hospital, Glasgow) said that enthusiasm for the treatment of tuberculosis by artificial sunlight, as for any new therapeutic procedure, was apt to exaggerate its possibilities, but light irradiation could play a useful and important part in the treatment of tuberculosis. Heliotherapy was difficult to carry out in these islands because of the fitful appearances of the sun and the relatively weak actinic value of its rays coming from skies blotted out by clouds of smoke. The systematic treatment of tuberculosis by artificial sunlight had been commenced in Glasgow in January, 1925; two 75-ampere and three 20-ampere lamps, running at 70 volts of continuous current, were used. Treatment consisted of a general light bath, the patient being naked except for short pants. An initial exposure to the carbon arc lamp of twenty minutes was increased every fourth day by five minutes. With the tungsten arc a shorter exposure of about two minutes, gradually increased to twenty minutes, was sufficient. The duration of exposure to the mercury vapour lamp was also short—between two and four minutes, gradually increased. The intensity of the reaction produced varied considerably, and careful supervision of the

treatment was therefore necessary: Protection of the eyes was also very necessary, because intense conjunctivitis sometimes developed eight or ten hours after the exposure, often during the night; it subsided, however, in a day or so, leaving no traces. Many cases of gland lesions had been treated, some of them complicated by ulcers and sinuses, and in all improvement had rapidly resulted. Over fifty cases of bone and joint tuberculosis had been treated, with excellent results; not only chronic sinuses healed, but in many cases there had been restoration of mobility and function in the joint, and x-ray plates had shown a return to normal of the bony structure. Cases of visceral tuberculosis required careful selection and constant supervision during treatment because a violent focal reaction, with increase of pulse rate and elevation of temperature, sometimes resulted. Cases of *tubercles mesenterica* were often greatly benefited, and sometimes large palpable gland masses diminished steadily under artificial sunlight treatment. Pulmonary tuberculosis had been treated in twenty patients, and though an increase of pulse rate had sometimes been noticed no ill results had followed, and practically all the cases had gained weight. He thought that in early cases great benefit might be derived from the tonic effects of the light.

#### *The Smoke Problem.*

Ex-Baillie W. BROWNELL SMITH, O.B.E., described the attempts made by the Glasgow gas department to introduce the use of gas for commercial heating and to provide smokeless fuel for the use of the citizens.

#### *Inspections and Demonstrations.*

On the afternoon of July 2nd visits were paid to corporation housing schemes, hospitals, and sanatoriums, and on July 3rd a demonstration was given by Dr. FERGUS L. HENDERSON of radiograms of the chest in tuberculosis and allied conditions, and various sanatoriums and dispensaries devoted to work in connexion with tuberculosis were visited.

#### *Annual Meeting.*

At the twenty-seventh general meeting of the National Association for the Prevention of Tuberculosis held at the close of the afternoon session of the conference on July 1st the annual report was adopted, on the motion of the Hon. Sir ARTHUR STANLEY, who was in the chair, seconded by Sir ROBERT PHILIP. The chairman referred to the special appeal about to be made to raise £100,000 for a three years' intensive campaign of popular education regarding the cause and prevention of the disease and for rendering communal and individual aid and making provision for the after-care of patients. In the evening a reception was held by the Corporation in the City Chambers, at which Lord Provost Sir Matthew W. Montgomery and the magistrates received the guests, and addresses were given in the banqueting hall.

### TWENTY-FIRST ANNIVERSARY OF THE UNIVERSITY OF SHEFFIELD.

On July 1st and 2nd the University of Sheffield celebrated its coming of age. King Edward VII opened the University in 1905, and the present celebrations were attended by Princess Mary. Glorious summer weather prevailed, and the thinning of the customary veil of smoke gave the city a strangely unfamiliar appearance, and justified the remark in a local paper, that Sheffield was one of Nature's beauty spots spoiled by being converted into an industrial city.

The University buildings are pleasantly situated on the lower slopes of Weston Park. In the park, a stone's throw from the entrance to the University, is the beautiful war memorial erected to the memory of the 8,814 non-commissioned officers and men of the York and Lancaster regiment who fell in the war. July 1st, the anniversary of the opening of the battle of the Somme, is the day of Sheffield's saddest memories; ten years ago a battalion recruited in this city was almost obliterated at Serre. An undertone of sadness mingled, therefore, with the dominant

chord of congratulation and jubilation. The ceremonial programme included the unveiling by the Chancellor of a war memorial in the University Library to the students who gave their lives in the war, and the laying of the foundation stone of a new sports pavilion on the University playing fields at Norton, given by a former Pro-Chancellor, the late Sir Albert Hobson, as a memorial to his two sons.

On Thursday morning, July 1st, the representatives of learned societies and other bodies were welcomed in the Firth Hall of the University by the Chancellor, the Marquess of Crewe, British Ambassador to France, and by the Vice-Chancellor, Sir Henry Hadow. The gathering was a most distinguished and brilliant one, and emphasized, as so many gatherings in recent years have done, the unification, geographically speaking, of the whole world. Saskatoon, Hong-Kong, Calcutta, Capetown, as well as many other distant places, sent delegates, and the University of Paris honoured Sheffield by sending representatives. The university spirit is evidently one of the factors contributing towards the evolution of the international—and interracial—mind. Sir Walter Fletcher represented the Medical Research Council, Professor J. S. Haldane was one of the delegates from Oxford University, and Dr. J. G. Adami came from the University of Liverpool.

Professor Bower, who represented the Royal Society, referred in his speech to the valuable influence of universities in great industrial cities, such as Sheffield, Manchester, Leeds, Liverpool, and Birmingham, in endowing their citizens with a wider outlook and the corporate spirit. The Marquess of Crewe, sounding a similar note, suggested that the infusion of the university spirit into industry would go far to remedy our industrial troubles. In the afternoon Princess Mary attended a Degree Congregation in the Victoria Hall, and received an honorary degree, as did also Sir Austen Chamberlain, Professor P. F. Frankland, Sir Hugh P. Allen, Miss Emily Penrose, and others.

On July 2nd the Marquess of Crewe, unveiling the war memorial, referred to the belief that, in spite of all its horrors, war as a cleansing fire might have a regenerating effect on nations. It was to be hoped that the last war had produced a hatred and horror of war such as had never existed before; this feeling was nowhere more profound than in France.

The delegates then attended the laying of the foundation stone of a gymnasium for the University by Mrs. H. K. Stephenson, and visited the applied science department of the University in St. George's Square, where new research laboratories for engineering and metallurgy were opened by Sir Robert Hadfield. The Marquess of Crewe referred to the good work of Sir Robert Hadfield in promoting a cordial understanding between the leaders of the steel industry in England and France, and Sir Robert Hadfield, touching on the question of unemployment, said it would be alleviated when, by increased output per man, the cost of production was brought down to an economic level. This increase in production depended on the enlightened goodwill of the worker himself; without this all other measures must be vain. Next came the use of every improvement in processes, materials, and plant, and in devising and adopting these the students of the University would play an important part. The visitors later made a tour of the finely equipped workshops and laboratories.

In the afternoon, after the opening of the Hobson Memorial Pavilion at the University playing fields, a cricket match between Sheffield and Liverpool Universities ended in a victory for Sheffield, and a conversation at the University in the evening concluded the programme for the day. An interesting series of demonstrations and exhibits in the laboratories of the medical school was given. In the department of pathology Dr. Godfrey Carter, professor of medical jurisprudence, gave a demonstration on the recognition of old blood stains; Dr. E. F. Skinner illustrated blood grouping for transfusion; Professor Douglas dealt with the factors in the acquisition of immunity; Mr. Froggatt, in the new laboratory for mechanical dentistry opened last year, showed the melting, rolling into plate, and drawing into wire of gold scrap.

In the physiology department demonstrations were given of the isolated, beating heart of the frog and of the rabbit, and the spectroscopic appearance of the blood in different conditions. The anatomy department furnished anthropological demonstrations by Mr. J. H. Cobb and Dr. F. Barnes of the bones of primitive man and the crania and skeletons of various living races. Professor Patten showed some interesting exhibits from his ornithological collection, and models in the anatomical museum were exhibited by Dr. Eric Stacey.

The Medical School of Sheffield is much older than the University; it dates back to 1828, and is looking forward to celebrating its centenary two years hence. For this reason it has been content to occupy a somewhat less conspicuous place in the present celebrations than might otherwise have been the case.

## SCOTTISH BOARD OF HEALTH.

### ANNUAL REPORT FOR 1925.

THE annual report of the Scottish Board of Health for the year 1925, which has just been issued, contains some new features, dealing especially with pneumonia, venereal diseases, rickets, and the value of the "health week." The question of medical certification of incapacity for work under national health insurance also receives special treatment.

The total death rate for Scotland in 1925 was 13.4 per 1,000 persons living, which is 1.0 less than for 1924, and 1.4 less than the mean of the rates for the last ten years. The death rates from pulmonary and non-pulmonary tuberculosis are the lowest yet recorded. On the other hand, the common infectious diseases in the sixteen large towns show a slight increase in total incidence during 1925, although there was a decrease in the death rate from these causes per 1,000 persons living. The infantile mortality also appears to have been considerably lowered. The death rate of children under 1 year of age was 90.5 per 1,000 births during 1925, which was lower than that of any previous year, excepting 1921 and 1923. It is pointed out that this progressive decline in the infantile mortality does not yet represent the full saving in health and life of infants that might be effected. The report refers to the findings of the Hospital Services (Scotland) Committee, presented in January, 1926, and states that of the additional 3,500 beds for general hospital work which the committee considered were required 1,000 are needed for the insured population. With regard to the housing shortage, the report states that the number of houses completed with State assistance for the working classes during 1925 was over 8,000, and that while this was an advance on the figures for the two preceding years it was not so great as was expected. The number under construction on the last day of the year was 13,311, and it is therefore expected that during 1926 a greater number will be completed than in any year since local authorities undertook this matter. The Milk and Dairies (Scotland) Act, 1914, was put into operation on September 1st, 1925, along with the Tuberculosis Order, which will have the effect of eliminating the dairy cows that give tuberculous milk.

### Housing.

The report states that a production of 20,000 houses a year is required in Scotland, and that it is regrettable that less than one-half this number have been finished during 1925. A conference of the larger local authorities was held in Edinburgh in July, 1925, at which the serious nature of the situation was discussed and a committee of local authorities appointed to investigate the causes of delay. A report issued in November, 1925, attributed the delay to the more stringent conditions of trade unions in Scotland and to the difficulty experienced by local authorities in borrowing money for housing purposes, as well as to a shortage of building trade labour. In December the Prime Minister announced that the Government had resolved itself to erect in Scotland 2,000 houses of the steel type, which did not require in their production and erection more than 10 per cent. of skilled building

trade labour, and at the close of the year active steps were being taken to put this scheme into operation. At the same time, the promotion of schemes by ordinary methods of construction was being pushed forward. On December 31st there were 63,937 houses completed, in course of erection, or immediately contemplated with the aid of the Government subsidies. Returns furnished by local authorities showed that 1,852 houses had been erected by unassisted private enterprise during 1925. A special grant had been made by the Treasury to enable local authorities to erect a small number of houses in different parts of the country for the purpose of demonstrating the value of steel houses, and in all twenty-four demonstration houses of the Weir and Atholl types had been allocated for this purpose. Local authorities had in all cases reported that the tenants had been perfectly satisfied with the comfort of steel houses, which were quite cool in the summer months and warm in the winter, little or no difference being presented between the steel house and the stone or brick house. Some difficulty had been experienced in regard to the housing of farm workers. Excepting to the extent that such workers might occupy houses provided by local authorities in villages adjoining the farms, it had not been practicable to provide houses for them through the agency of the local authorities. It had been urged from time to time that grants should be made available to owners of property in rural areas towards the cost of improvement and repairs in existing houses, as this would be a more economical method of providing suitable accommodation than the erection of new houses, and this proposal had engaged attention during the year. With regard to slum clearance during the year, the Board of Health had confirmed five improvement schemes and one reconstruction scheme in the burghs of Buckhaven, Dunbar, Dundee, Leith, Leven, and Perth. With the assistance of the slum clearance grant, thirty-six local authorities were proceeding with schemes which involved the closure of 7,904 houses, to replace which 7,450 houses were being constructed. It is pointed out that considerable difficulty is found in rehousing the tenants from insanitary areas, as tenants are often unwilling to remove to the new houses provided for them, despite the fact that the new rents are often lower than those previously paid.

### Venereal Diseases.

During the year 1925 the number of venereal treatment centres had been increased to forty-five. With regard to syphilis, it is stated that if a case is treated before the parasites have become generally diffused through the body, and if treatment is vigorously carried out, a cure may be anticipated with confidence; that in the next stage, while a cure is still to be expected, the success of treatment cannot be promised with the same assurance, and the duration of treatment is more protracted, although immediate palliative results are the rule. The most important feature in treatment is, therefore, that it should be commenced at the earliest possible date. It is pointed out that the use of mercury as a remedy has not been displaced by the introduction of arsenobenzol products, but that of recent years bismuth has, to a considerable extent, replaced the use of mercury compounds, while potassium iodide in certain circumstances is still found to achieve results that cannot be produced by any other preparation. The accepted standard of cure is that the blood of the patient must give negative responses to Wassermann tests for a period of two years.

In the treatment of acute anterior gonorrhoeal urethritis irrigation by warm solution of suitable antiseptic conveyed by means of a siphon is recommended. The antiseptic preparations mentioned are potassium permanganate (1 in 8,000 to 1 in 4,000), zinc sulphocarbonate (1 in 4,000), mercury oxycyanide (1 in 4,000), silver nitrate, and mercurochrome. The report states that the value of treatment by vaccines is still in doubt. It is believed that between 35,000 and 70,000 new cases of gonorrhoea occur in Scotland annually, and that a large proportion of them receive no satisfactory treatment. It is believed further that, of all the grave maladies, none has been more neglected and none has had its dangers less clearly realized.

A certain amount of propaganda for instruction had been arranged by individual local authorities, and the bulk of this work had been efficiently carried out by the Scottish Committee of the British Social Hygiene Council, to whom a grant of £800 was paid towards the cost of an approved programme during 1924-25. The Council's activities, at the suggestion of the Board of Health, had been especially directed to those areas in which least advantage had been taken of the public facilities provided for treatment.

#### *Pneumonia.*

The report observes that while far more public interest is devoted to tuberculosis than to pneumonia, the annual deaths from pneumonia in Scotland average between 6,000 and 7,000, while the deaths from pulmonary tuberculosis are under 4,000. The death rate from most of the acute diseases has fallen in the last seventy years, but pneumonia forms an important exception. The mean death rate from pneumonia in the period 1921-25 was roughly 70 per cent. higher than in the period 1855-60. With regard to the reasons for this increased death rate, it was suggested that a number of conditions formerly diagnosed as tuberculous are now regarded as pneumonia, and that epidemics of influenza have undoubtedly affected the pneumonia death rates in some years. It is estimated that since one out of every five persons suffering from pneumonia dies of the disease, there must be between 30,000 and 35,000 cases in Scotland in an average year, apart from cases of secondary pneumonia following measles and whooping-cough. Of the four varieties of pneumococcus recognized in pneumonia, Type I is responsible for about one-third of the cases of acute lobar pneumonia, but Type III is the most fatal. Certain local authorities (Glasgow, Aberdeen Burgh, and Aberdeen County) had undertaken to admit to their hospitals any pneumonia patients whose doctors recommended removal. It is suggested that hospital treatment is the ideal to be aimed at wherever possible, and that, with modern methods of transport, it is safe to remove to hospital a patient suffering from pneumonia up to the fourth or fifth day of the illness, except where signs of cardiac embarrassment are present. In the city of Glasgow the number of cases admitted to hospital during the year was 3,034, as compared with 476 cases in 1919. A serum is now available for the treatment of pneumonia due to the pneumococcus of Type I, but its efficacy is still a matter of doubt. The object of removing cases to the local authority's hospitals has been to increase largely the number of beds available for pneumonia patients.

#### *Rickets.*

A special investigation of rickets was made during the year by the Board of Health. Returns made by child welfare centres showed that in seven burghs among 15,114 children attending for the first time there were 683 cases of rickets, or 4.5 per cent., among all such children. In three out of these seven areas the percentages were as high as 10.5, 15, and 54.6 per cent. Returns received from school medical officers showed that out of 179,502 children examined in twenty-two areas, 1,623 were recorded as having had "slight" rickets and 2,359 "marked" rickets. The total percentage for rickets in these areas was thus 2.2. Out of 3,742 children examined on entering school at Aberdeen, 39.9 per cent. of the boys showed traces of rickets and 34.7 of the girls, or more than one in three of the 5-year-old children. Somewhat similar results are yielded in the schools of other areas. The medical officer of health for Glasgow is quoted as having stated that among children between the ages of 6 months and 10 years examined in Glasgow hospitals, 40 per cent. were suffering from rickets. With regard to the influences connected with the production of rickets, returns from Dundee appear to indicate that the percentage of children with rickets was precisely the same—namely, 50 per cent.—no matter what the size of the house from which they came. With regard to feeding, among 290 cases of rickets, 172 were breast-fed for six months or more, 40 were partly breast-fed and partly bottle-fed, and 92 were bottle-fed. The Board considers that it has been fairly well established that vitamin A is a growth-promoting and not a

rickets-preventing vitamin, the latter being now known as vitamin D and having a distribution similar to vitamin A but being distinct from it. The explanation of the value of ultra-violet light treatment in cases of rickets was probably to be found in the fact that cholesterol, when exposed to ultra-violet rays, acquired antirachitic properties. The report gives details of the results obtained by the latter means at the Carnegie Clinics at Motherwell and elsewhere.

#### *Maternity Service and Child Welfare.*

While the infantile mortality rate is on the whole decreasing there is little indication that puerperal mortality is on the wane. The Registrar-General's returns are quoted as showing that the death rate of mothers per 1,000 births, which was 5.1 in 1865, had risen to 6.1 in 1915 and was 6.2 in 1925. Maternity service and child welfare schemes are now in existence for areas including 92 per cent. of the total population of Scotland. Broadly, therefore, thirteen out of every fourteen of the women and children in Scotland have available to them the services of the local authorities. These schemes differ in completeness, but their extent may be gathered from the fact that the total number of visits made by health visitors during the year was 632,202; of these, 22,561 were to expectant mothers and the remainder to children; of the latter, 67,680 were first visits to newly born infants. The number of health visitors employed by local authorities was 141 whole-time visitors and 417 part-time health visitors. In all there were 196 maternity and child welfare centres in operation, at which there was a total number of attendances of 315,437 during 1925. The number of children who attended for the first time was 20,365, and the number of women who attended for ante-natal consultation was 8,178. The number of centres under the schemes at which special treatment is provided was forty-seven. About one-third of the births occurring in the areas for which figures are available were attended by midwives, and in approximately 5,000 out of these 30,000 births the midwives called upon the assistance of a medical practitioner in emergency.

#### *The Food Supply.*

The report indicates that considerable developments took place under the Sale of Food and Drugs Acts during 1925. The Milk and Dairies (Scotland) Act came into operation on September 1st, 1925, as did also the Tuberculosis Order by the Ministry of Agriculture, and the Preservatives in Food Regulations (Scotland) were introduced on August 17th. In terms of the Dairies Act, all dairy cows in Scotland would be subject to veterinary inspection at least once every year, although in towns and cities veterinary inspection of cows will be carried out with much greater frequency. Local authorities had already shown great interest in the supply of clean milk, and the system of licences for the sale of higher grade milk had made definite progress. Only two preservatives (sulphur dioxide and benzoic acid) will be allowed in food after January 1st, 1927, and the staple articles of diet, such as milk, butter, cream, eggs, meat, and fish, will be entirely free from preservatives after the regulations come into operation. The total number of samples of foods submitted to public analysts was 7,635, and of these 778 were found adulterated or not up to the proper standard, the greater number of these (604) being samples of milk.

#### *Health Weeks.*

Of the systematic efforts made to educate the public in communal and personal hygiene the holding of a well organized "health week" is commended. The central feature of a health week should be an exhibition of a varied character, including exhibits connected with all the medical services provided by the local authority and by voluntary agencies, such as the Red Cross Society, St. Andrew's Ambulance Association, etc. It is suggested that a section should be devoted to child welfare, another to tuberculosis, and another to food, cooking, and invalid diet. Reference is made to a very successful health week held in Aberdeen in October, 1925, at which the average attendance was 3,500 each day.

*Insurance.*

In the year 1925 the number of persons insured with approved societies was approximately 1,650,000. Of these, many thousands received sickness benefit under medical certification. During the year 22,515 cases, which had been medically certified, were contested and referred to medical referees. Of these, 41 per cent. were confirmed, 21 per cent. were not confirmed, and 38 per cent. failed to appear. Records had been kept of these examinations, and some classified results are presented in the report. It appears that there was a special tendency for patients to desire to remain as long as possible on the sick list in cases of anaemia, debility following pregnancy, and various rheumatic affections. In the case of anaemia, 90 per cent. of the referred cases had been found capable of work on examination. In one region special attention had been concentrated on heart disease as the cause of incapacity for work. Among 3,000 heart cases, 285 patients (9.5 per cent.) had been found to be incapacitated by heart disease of some sort.

The report concludes with some general remarks upon such subjects as the welfare of the blind, the organization of consultative councils, the remuneration of medical officers, and the examination and certification of nurses.

## ROYAL SANITARY INSTITUTE.

### JUBILEE CONGRESS.

THE jubilee congress of the Royal Sanitary Institute opened in London on July 5th and continued for the four following days. Some hundreds of municipalities were represented, as well as Government departments and professional organizations. The British Medical Association was officially represented by Dr. H. B. Brackenbury and Dr. I. W. Johnson. The events of the week began with a luncheon, over which the DUKE OF NORTHUMBERLAND presided. Sir ARCHIBALD GARROD, Regius Professor of Medicine at Oxford, in proposing "Success to the Congress," recalled the sanitary conditions of the eighteenth century, at the time the Institute was founded, and said that there was no department of science which could compare with preventive medicine in its achievements during the last half-century.

### *Inaugural Address by the Minister of Health.*

The representatives assembled at the Guildhall for the inaugural address by the President of the Congress, Mr. NEVILLE CHAMBERLAIN, Minister of Health. Owing to his duties at the House of Commons, where he was expected to introduce the Boards of Guardians (Default) Bill, Mr. Chamberlain could not remain more than a few moments, and he contented himself with giving a welcome to the representatives, and saying that he and his colleagues at the Ministry regarded themselves as partners with sanitarians in the great work of preventive medicine. During the period covered by the Institute's activities the science of sanitation had been taken at a bound from the Middle Ages to its present efficiency.

Mr. Chamberlain's inaugural address, which was read for him by Mr. I. G. Gimmon, one of the assistant secretaries of the Ministry, was a summary of sanitary progress since the passing of the Public Health Act, 1875, which still stood, he said, although there had been subsequent enactments, as the foundation of public health legislation. That Act was itself a consolidation, and the time was ripe for a fresh consolidation, and measures to that end were being taken. After reviewing the present situation with regard to infant mortality and other matters, he said that there was some danger lest, because conditions were so much improved, precautions should be relaxed. The precaution of vaccination, for example, was not observed to nearly the extent that was desirable, and there was room for further education of public opinion on that subject. Turning to the directions of future effort, Mr. Chamberlain referred to the need which still existed, particularly in many rural districts, for simple measures of sanitation adapted to local means and circumstances. The Smoke Abatement Bill, to which the House of Commons had given

a second reading, offered another opportunity for progress. A further field was the supervision of milk and other food supplies; here it was necessary to walk circumspectly lest scarcity be created by the zeal for purity. With regard to housing, since 1919 more than 670,000 houses had been built, over 413,000 of them with assistance from the Exchequer, and, with the same assistance, a further 224,000 were in course of erection or had been authorized. He had some further measures in contemplation dealing with rural housing. He also touched on the scheme of Poor Law reform which he had circulated for consideration. It was vitally important that the health work now undertaken by Poor Law authorities should be brought into closer relation with that which was done by other bodies. He hoped also that some means would be found of bringing the work of the great voluntary hospitals into closer relation with the work done by public authorities, though he had a strong conviction with regard to the need for maintaining the voluntary character of the hospitals, and would do nothing to impair that character. Finally, he spoke of the need and appreciation of research, saying that he regarded it as necessary that among the medical profession and health workers there should be that general attitude of mind which fostered research, and among the general public a greater appreciation of the value of such work. The reason why English preventive medicine had always been in the forefront was because of the existence of a well informed public opinion.

The vote of thanks to Mr. Chamberlain was proposed by Professor A. BOSTOCK HILL, chairman of council of the Institute, and was spoken to by Sir MATTHEW NATHAN, Professor L. FRIDERICIA, representing the Home Office of Denmark, who said that the modern sanitary movement was born in England, as Denmark was happy to acknowledge, Colonel C. A. GILL, I.M.S., who spoke on behalf of the dominion and colonial representatives, and Alderman EDMONDSON, mayor of Carlisle, on behalf of the municipal authorities.

### *The Preventive Aspects of Medicine.*

The Section of Sanitary Science and Preventive Medicine was opened with an eloquent address by Sir GEORGE NEWMAN, the President of the Section. He described disease as a disharmony within the body which had to be avoided or corrected. The germs of disease were important, but he begged people not to go "germ-mad." The essential thing was the health and resistance of the body. Progress depended more upon social evolution than upon the advance of sanitary science as such. It depended more upon wisdom than upon knowledge. Knowledge and wisdom, far from being one and the same, had oftentimes no connexion. Knowledge was the mere material upon which wisdom built. Lord RIDDELL delivered an amusing essay in this Section on the press and preventive medicine. In the discussion that followed one or two useful points were elicited. Mr. H. LESSER, chairman of the London Insurance Committee, said that his administrative work had made him mourn at the smallness of the proportion of the insured population who realized that national health insurance was an integral part of preventive medicine. Dr. SHADICK HIGGINS, medical officer of health for Capetown, said that in South Africa there was no difficulty in getting the press to publish whatever the medical department wanted. The difficulty was rather for the medical officer of health to prove himself equal to the occasion, and take advantage of the facilities offered. Sir GEORGE NEWMAN remarked that neither the public health officers nor the officials in Whitehall could "deliver the goods" unless there was an educated people.

At the Mansion House on the same morning, at a conference of representatives of sanitary authorities, Dr. G. CLARK TROTTER dealt with a similar subject, "Public health propaganda in its practical aspects." He gave an account of various forms of publicity, and stressed the importance of distinguishing the reasoned and authoritative advice on health from the mass of camouflaged advertising propaganda with which the country was at present flooded.

The first of the technical papers in the Sanitary Science Section was by Major A. G. R. FOULERTON, who spoke of

the place of bacteriology in preventive medicine, and traced the work done in the recent war in shielding the British Army from infections. Dr. A. F. TRENCH spoke of the place of inheritance in preventive medicine. The factor of inheritance, he said, unlike that of environment, was little appreciated, but although not much was known of the mechanism whereby it was brought about the fact of inheritance was obvious and indisputable. He did not think it could be questioned that even susceptibility and immunity to the action of micro-organisms was largely a matter of inheritance. While far from deprecating efforts directed towards the improvement of surroundings, he pointed out that there existed in the community a very large number of persons in whom innate tendencies to physical defect and ill-health were so marked that, whatever the environment, their offspring were likely to be similarly handicapped. This led up to a plea for a place for eugenics in the science, practice, and teaching of preventive medicine. The final paper of this session was by Dr. H. P. NEWSHOLME, who spoke of the influence of the healthy mind in preventing bodily ill-health. His argument was that preventive medicine could not be wholly preventive until it included the mind in its province.

In the Section of School Hygiene Professor WINIFRED CULLIS and Dr. LEONARD HILL opened a discussion on the recommendations made to the Board of Education Advisory Committee with reference to the introduction of physiology into schools, and this was followed by a discussion on colds and catarrhal conditions, opened by Dr. CLIVE RIVIERE, followed by Dr. A. I. SIMES and Dr. L. R. LEMPIERE.

#### *The Rheumatic Child.*

Papers on rheumatism were contributed by two members of the special subcommittee of inquiry into heart disease in children, set up by the British Medical Association, whose report was published as a special SUPPLEMENT to the last issue of the BRITISH MEDICAL JOURNAL. Dr. CAREY F. COOMBS said that the report in question included a comprehensive summary of the institutional provision available in this country for prolonged treatment of rheumatic infection. This was a tale of fragmentary and imperfect effort, which made a poor show when compared with the generous accommodation afforded in America for children suffering from such conditions. There existed an American Heart Association which had done great things on behalf of cardiac invalids in general and the rheumatic child in particular. In the earlier stages of cardiac rheumatism a certain percentage of recoveries could be claimed. He knew of no way in which that percentage could be increased except by prolonged and efficient institutional treatment. The treatment of rheumatic children in a school hospital would help to teach the public, as well as the profession, what were the principles of defence against this infection. The other paper was by Dr. F. J. POYNOR, who laid stress upon the gravity of the condition of acute rheumatism in the young, the need for further study of its causation, and of the associated nerve strain, and the environmental, dietetic and epidemiological factors. He was convinced by clinical and experimental evidence that the tonsils were a site of access of this infection. Statistics would not shake him in this belief, but it was not to be supposed that that was the only site. Another step in prevention to which he looked forward was the establishment of a central institute for the study of "rheumatism." It was a wasteful policy to be content with isolated investigations. A properly organized institute could do continuous work, train investigators, and collect information.

Sir GEORGE NEWMAN said that it was high time something definite was done about rheumatism, and he rejoiced that it had a place in the programme of the Congress. Progress in preventive medicine did not lie in repeating the old shibboleths about environment, but in a new grasp and understanding of the group of diseases which invalidated the people. Dr. IZOD BENNETT spoke of the intestine in relation to the occurrence of chronic rheumatism, and blamed the widespread use of preserved foodstuffs for the invasion of the bowels by dangerous micro-organisms. Dr. REGINALD MILLER dealt with the environmental factors producing the rheumatic child, and quoted the facts elicited

by the British Medical Association's subcommittee, of which he was secretary. Dr. JAMES WHEATLEY (Shropshire) and other medical officers of health joined in the discussion, which chiefly concerned the questions of bad housing, damp soil, and other predisposing factors.

#### *Midwifery in the Home.*

On Wednesday morning a joint session was held with the Maternity and Child Welfare Conference, under the presidency of Lady FORSTER OF LEE, when the subject for discussion was midwifery in the homes of the people.

Dr. T. WATTS EDEN, in opening from the consultant's point of view, said that the conduct of labour was a surgical procedure; it might be of the simplest surgical character, or developments might occur to transform it into a major surgical operation. The surgical requirements which must be regarded as the minimum of safety in the home included the services of a trained midwifery nurse. No doctor ought to be expected to attend a confinement without the help which such a nurse could give him. It was a national disgrace that "handy women" were still allowed to ply their evil calling. These unclean anachronisms, reminiscent of the bad days which produced Sairey Gamp, were one of the most potent influences in maintaining the high rate of puerperal sepsis. The public attitude in recent years had been a little unfair to doctors, especially to the family doctor. Not all the emergencies of confinement were capable of being foretold by the most careful medical supervision. Assuming an adequate degree of care and skill on the part of the doctor and nurse, they were no more to be held blameworthy for the casualties of midwifery than for the unfavourable termination of a medical or surgical illness.

Dr. W. ALLEN DALEY (M.O.H. Hull), speaking of the need for better training of the midwife and of the doctor in midwifery, said that between 1,000 and 2,000 preventable maternal deaths still took place in this country every year, and thousands of cases of chronic ill-health resulted from bad midwifery. There should be collaboration between the private doctor, the private midwife, and the local authority's medical and nursing staff.

Dr. E. KAYE LE FLEMING (British Medical Association) said that the conditions under which the general practitioner had to perform his duty often varied widely from the ideal. In many cases they made ordinary (not to speak of surgical) cleanliness impossible. But the very difficulties which the general practitioner encountered, and his wide experience single-handed, developed his skill, resource, and independence, and made him a real specialist in midwifery. No case gave the general practitioner more anxiety than a maternity case which developed complications during the puerperium. The speaker dissented from some popular conclusions based on the statistics of puerperal fever. Apart from the unreliability of figures taken from selected areas and relating to an ill defined condition, a large number of these cases arose when labour had been apparently normal, and free from interference by nurse or doctor. On the other hand, cases in which many factors favouring sepsis were present frequently ran a normal course. Some unknown factor must be invoked to explain the complication—possibly an unrecognized influence tending to diminish the normal personal resistance to infection. Speaking generally, after an experience of twenty-five years in town and country practice, he was convinced that there had been the same steady advance in the treatment of maternity cases as in medicine and surgery generally and in public health. This had been assisted by the quickening of the means of communication, the advance of the general standard of cleanliness in the home, the steady replacement of the "handy woman" by the trained midwife, and the earlier recognition of complicated cases, with the provision of hospital accommodation for them. It was along these lines that continued improvement must be looked for. More ante-natal and post-natal clinics must be established, the former especially to detect cases of possible pelvic malformation and independent disease.

A large number of speakers joined in the discussion, including some from overseas. Dr. DICKINSON (New York) said that in New York it was the object to ensure, not indeed one bed for every maternity case, but one bed in an obstetric institution (or at least attendance by an

obstetrician of skill) for every first confinement. Dr. C. N. BENTLEY (Bengal) said that in the Indian province he represented, with the same population as Great Britain and Ireland, one and a half million births took place in a year. Only one-half the children born reached the age of 8 years. No fewer than 35,000 infants and nearly 10,000 mothers died of tetanus within a few days of delivery. The reason for this appalling death rate was ignorant midwifery. Dr. LEON JONA (Victorian Branch of the British Medical Association) said that he looked forward to the day when midwifery would be in the hands of specialist practitioners only. As regards nursing, he believed conditions in Australia were better than in Great Britain.

#### CONFERENCE ON MATERNITY AND CHILD WELFARE.

The fourth English-speaking Conference on Maternity and Child Welfare was held in London from July 5th to 8th, and was attended by over seven hundred delegates, the majority of them from public health authorities. The Conference was opened by Sir H. KINGSLEY WOOD, M.P., Parliamentary Secretary to the Ministry of Health, who gave a number of figures illustrating recent progress in the prevention of infant mortality. He deplored the fact that maternal mortality had shown practically no diminution during the last twenty years. Moreover the lessened infant death rate appertained almost wholly to infants after the first month of life. It was the object of the Ministry of Health to create an informed public opinion with regard to maternal mortality, and in this connexion he was glad to say that the number of ante-natal centres had increased during the last two years from 564 to 641, and the number of infant welfare centres from 2,011 to 2,218. The services of trained midwives were now available for nearly 70 per cent. of the rural population.

Dame JANET CAMPBELL introduced the subject of the health of children of from 1 to 5 years. She showed that there had been a general downward tendency in the rate of mortality of children of this age, though there was still room for improvement. Health visitors at present concentrated on the infant, and the little being whom she called the "ex-baby" was likely to be neglected. Competent health visiting, with its many occasions for teaching the mother the importance of mental and physical hygiene, would do more than anything else to raise the standard of health among pre-school children. She also suggested special sessions at infant welfare centres at which children up to 5 years of age might be examined by the doctor two or three times a year. There should also be increased facilities for the treatment of certain defects, such as orthopaedic conditions. The remainder of this discussion was chiefly taken up by the recitation of American experience by three or four visitors from the States.

#### Conception Control Teaching at Welfare Centres.

A discussion, which was so eager and animated that it took double the time allotted to it on the programme, was on a question which was set out as: "Should medical officers be free to give information on birth control at centres in individual cases?" but which might be more accurately stated as: "Should women as a right receive information on conception control from medical officers at welfare centres?"

Dr. MARGARET EMSLIE, maternity and child welfare medical officer for Croydon, maintained the affirmative, with certain reservations. Her view was that individuals did stand in need of such advice, and that the centre doctor was the best person to give it. She agreed that it would be calamitous if the infant welfare centres became associated in the public mind with the question of conception control *per se*, and she was strongly against miscellaneous instruction; the instruction should be given only in the individual case, and there only on medical grounds or where medical and economic considerations could not be dissociated. She begged those who were hostile to this proposal to give its supporters credit for a moral position. Dr. MARY BLAIR, medical officer of the Hammersmith Centre, took a different view. Whatever the merits of conception control, the infant welfare centre was essen-

tially a health centre, not a resort for the diseased and defective. If it was urged that a woman with phthisis should expect to receive advice on conception control at the centre, the answer was that such a woman had no business there at all; she ought to be under the tuberculosis authorities. Dr. BLAIR maintained that at the centres what should be taught was the ideal, not the expedient thing. The whole atmosphere of the centres would be lowered if this information were imparted, though she did not think there would be any harm in teaching restraint and continence and knowledge as to certain times in the reproductive cycle. But conception control could not be taught without teaching mechanical methods, which would be very unfortunate from the point of view of the influence of the centre. These speakers were followed by two working-class women, each of whom took a different view of the subject. Dr. ERIC PRITCHARD, who was in the chair, agreed with Dr. BLAIR. Dr. LETITIA FAIRFIELD also spoke strongly in opposition to the proposal. She said that speakers on the other side began with the assumption that a doctor by virtue of her medical degree should be allowed a wide discretion as to the giving of this advice. But was it right that a woman should allow a doctor to say that she had too many children or not? The infant welfare movement would be broken from top to bottom by any such introduction if it came to be regarded, as it would be, as an attempt to remedy economic ills. She admitted the hard cases, but such cases ought not to be allowed to govern the principle. What would very frequently happen would be that a woman who had had a bad first confinement would go down to the centre and receive this advice, and afterwards settle down into the neurotic mother of an only child. Dr. BERNIE DUNLOP took an opposite position, but he said that he would be satisfied if such teaching as was suggested by Dr. BLAIR were given at the centres. The fairly even division of opinion among the speakers was reflected in the audience. Cries of protest were made when one medical officer of a clinic declared that behind this demand was a desire to shirk motherhood, and she was answered by another speaker, who said that it was because working women were beginning to realize the dignity of motherhood that they desired to be taught conception control and the spacing of families. If such teaching were not given, the resort of many of these women would be to the criminal abortionist.

#### BIRTHDAY HONOURS.

The following honours have been conferred on members of the medical profession, on the occasion of His Majesty's birthday. Owing to the general strike publication of the list was deferred from June 3rd to July 3rd. To all the recipients, and in particular to Dame Mary Scharlieb and Sir Alexander MacCormick, we offer the congratulations of their colleagues.

##### K.C.M.G.

Colonel Sir ALEXANDER MACCORMICK, Kt., M.D., F.R.C.S.Ed., Honorary Consulting Surgeon, Prince Alfred Hospital, and Surgeon, St. Vincent Hospital, Sydney. In recognition of his service to the Commonwealth of Australia.

##### D.B.E. (Civil).

Mrs. MARY ANN DACOMB SCHARLIEB, C.B.E., M.D., M.S., Consulting Gynaecologist, Royal Free Hospital.

##### Knighthood.

ALFRED HENRY EVANS, M.R.C.S., L.S.A., J.P., Member of the Unionist Association of the Tamworth Division since 1895, and President and Chairman since 1920. For political and public services.

##### C.B. (Military).

Surgeon Captain REGINALD ST. GEORGE SMALLRIDGE BOND, M.B., F.R.C.S., R.N.

Major-General ROBERT STRICKLAND HANNAY, C.M.G., D.S.O., K.H.S., Deputy Director of Medical Services, Southern Command.

##### C.M.G.

JOHN OWEN SHINCORE, M.B., Ch.B., Director of Medical and Sanitary Services, Tanganyika Territory.

##### C.V.O.

ERNEST CLARKE, M.D., F.R.C.S., Consulting Surgeon, Central London Ophthalmic Hospital.

## WAR MEMORIAL HOSPITAL AT ANDOVER.

**C.I.E.**  
Colonel KRISHNAJI VISHNOO KUKDAY, I.M.S., Inspector-General of Civil Hospitals, Central Provinces.  
Lieut.-Colonel THOMAS WILLIAM HARLEY, I.M.S., District Medical and Sanitary Officer and Superintendent, Medical School, Madras, Madras.

**C.B.E. (Civil).**  
Colonel GEORGE WYKEHAM HERON, D.S.O., O.B.E., R.A.M.C. (ret.), Director of Department of Health, Palestine.

**O.B.E. (Military).**  
Temporary Captain WILLIAM BLIGH, M.D., R.A.M.C.  
Lieut.-Colonel HENRY ROBERT BROWN, I.M.S.  
Major WILLIAM EGAN, D.S.O., M.B., R.A.M.C., Deputy Assistant Director of Medical Services, Scottish Command.  
Major CHARLES HENRY HASLER HAROLD, M.D., R.A.M.C., Assistant Instructor, graded as Deputy Assistant Director of Hygiene, Aldershot.  
Captain (local Major) JOHN WRIGHT MALCOLM, M.C., M.B., R.A.M.C., attached Iraq Levies.

**M.B.E. (Military).**  
Captain WILLIAM DANIEL ARTHUR, R.A.M.C.

**O.B.E. (Civil).**  
ANANDRAI KESHAVLAL DALAL, F.R.C.S., Professor of Clinical and Operative Surgery, Grant Medical College, Bombay, and Surgeon, Jamsheetjee Jeejeebhoy Hospital, Bombay.  
DIGBY MACKENZIE MACPHEIL, M.B., C.M., Medical Officer, District 1, St. Lucia, Windward Islands.  
WILLIAM MACLACHLAN McDONALD, M.R.C.S., L.R.C.P., Medical Officer, District 2, Antigua, Leeward Islands.  
FRANK EDRED WHITEHEAD, M.R.C.S., L.R.C.P., Director of Military and Sanitary Services, Nyasaland Protectorate.

**M.B.E. (Civil).**  
Major JOSEPH HENRY ARNOLD DONNELLAND, I.M.D., House-Surgeon, Jamsheetjee Jeejeebhoy Hospital, Bombay.  
Major HENRY CLEMENT CRAGGS, I.M.D., Military Assistant Surgeon, Madras.  
ALAKH BEHARI ARORA, Medical Officer of Health, Lahore.

## WAR MEMORIAL HOSPITAL AT ANDOVER.

FIELD-MARSHAL VISCOUNT ALLENBY formally opened the War Memorial Hospital at Andover on June 30th. The building, which has just been completed, is erected on open land to the north of the town on a gentle slope to the south-south-west. The main wards projecting to the south form a wide sheltered and screened court for the use of patients. Every room in the hospital gets the full sun except those where it is not desirable, such as the operating room, the x-ray room, and the kitchens and offices, which have all been planned along the north side, with easy access to the patients' quarters on the south.

The main central corridor has been kept low to allow cross-ventilation to the private wards on the south side, and this has permitted considerable economy in construction. Heating is by a low pressure hot-water plant, though all wards have open fires in addition. The cooking will be by gas. The building is lighted by electricity. The main wards have been designed to give 100 superficial and 1,050 cubic feet per patient, and the private wards considerably more. All the windows in the wards are of the metal Austral type, and above them are additional windows of the hopper type, giving ventilation at the ceiling level. The two ward kitchens have been placed in such positions that they serve also as duty rooms to two wards in each case. There are large sun verandahs at the south end of the two main wards.

ANDOVER WAR MEMORIAL HOSPITAL.

serve these suggested additions without alterations. The architects are Mr. Edward Maufe, M.A., F.R.I.B.A., and Mr. Leslie Moore, M.C., F.R.I.B.A., of Raymond Buildings, Basingstoke. H.R.H. the Prince of Wales paid a private visit on June 29th to the hospital on his way to the railway station from Enham Village Centre, and made a careful inspection, at the end of which he expressed the opinion that was a very fitting memorial and that the town was to be congratulated on the possession of such an up-to-date hospital.

To be Honorary Member of the Civil Division of the Order of the British Empire.  
HALIM ABU RAHMEH, Medical Officer, Department of Health, Palestine.

**Kaisar-i-Hind Medal (First Class).**  
Miss AGNES SCOTT, M.B., Chief Medical Officer, Women's Medical Service, and Secretary, Countess of Dufferin's Fund.  
JOHN DAVID O'DONNELL, M.B.E., V.D., F.R.C.S.Ed., Chief Medical and Sanitary Officer, Kolar Gold Fields, Mysore.  
Major JOSEPH ALEXANDER H. HOLMES, I.M.D., Senior Assistant Surgeon, British Station Hospital, Quetta.

**Companion of the Imperial Service Order.**  
Major HERBERT WILLIAM V. COX, I.M.D., Civil Surgeon, Punjab.

**NAVAL PROMOTIONS.**  
The following promotions are announced in connexion with the King's Birthday honours:

**Royal Naval Medical Service.**—Surgeon Commanders to be Surgeon Captains: HERBERT R. H. DENNY, JOHN S. DUNDING, O.B.E., ARTHUR R. THOMAS, C.B.E., F.R.C.S., PERCIVAL T. NICHOLLS, JAMES MCCUTCHEON, M.B.  
**Royal Naval Volunteer Reserve.**—Surgeon Commander to be Surgeon Captain: ROBERT J. WILLAN, M.V.O., O.B.E., V.D., M.B., M.S., F.R.C.S. Surgeon Lieutenant Commanders to be Surgeon Commanders: FRANCIS H. WATSON, M.B., GEORGE H. S. MILLS, M.B. (Surgeon Commander, Emergency List, R.N.).

The name of Miss Agnes Hunt, of the Hospital for Cripples, Gobowen, near Oswestry, also appears among those upon whom the honour of D.B.E. is conferred. Over a quarter of a century ago (1900) she established on a small scale at Baschurch, near Shropshire, a hospital for cripple children in which the principle of open-air treatment was from the first carried out. She has with the assistance of other surgeons who volunteered their services, visited the hospital periodically in cases of bone which were found to be necessary, especially in cases of bone and joint tuberculosis. The hospital grew, and Miss Hunt organized a system of local clinics, by which cases requiring treatment were discovered. Afterwards the hospital was removed to a more commodious building near Oswestry. The principles for which Miss Hunt worked have been extended to other counties, and the Central Committee for the Care of Cripples was established. In congratulating Miss Hunt we congratulate also the medical profession, of which she is so beloved and distinguished a colleague.

The concrete foundations are laid on the solid chalk and all the outside walls are of hollow construction, being built of 9-inch internal brickwork, 2-inch cavity, and 4½-inch exterior brickwork, rendered in cement on the outside. The general character of the building is shown in the accompanying illustration from a drawing exhibited at the Royal Academy. The total cost of the building, providing twenty beds and three private wards, has been £16,000. The possibility of future additions has been kept in mind throughout, and the building can be readily extended at three separate points. The most pressing addition will probably be a maternity ward and a children's ward to the south-east at the end of the main corridor. The men's and women's wards can be extended considerably in length without affecting any other portions of the building. It is hoped that the administrative portions will be found sufficiently large to serve these suggested additions without alterations. The architects are Mr. Edward Maufe, M.A., F.R.I.B.A., and Mr. Leslie Moore, M.C., F.R.I.B.A., of Raymond Buildings, Basingstoke.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE. MAIN ELEVATION—KEPPEL STREET FRONT.

## THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

### FOUNDATION STONE LAID BY THE MINISTER OF HEALTH.

The foundation stone of the London School of Hygiene and Tropical Medicine was laid by Mr. Neville Chamberlain, Minister of Health, on the afternoon of July 7th.

Rather more than five years ago a committee was appointed by the Ministry of Health, with the Earl of Athlone as chairman, to investigate the needs of medical practitioners for further education in medicine in London. A memorandum was furnished to the committee by the British Medical Association, and in May, 1921, a report was issued by the committee advocating the establishment of a post-graduate medical school in London, and also of an Institute of State Medicine, both to be in association with the University of London. The committee's recommendations were published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL for July 16th, 1921 (p. 25). An expert committee, of which the Minister of Health was chairman, was appointed to consider the recommendation as to an Institute or College of Hygiene: the chief difficulty in the way of its realization was financial. The matter was placed before the Rockefeller Foundation, and in February, 1922, the Rockefeller Trustees generously offered two million dollars (£400,000) towards the cost of building an Institute or School of Hygiene in London on the understanding that the British Government would accept the responsibility of providing for the staffing and maintenance of the school when established; the cost of this was estimated at about £25,000 a year. A second donation of £4,000 yearly was subsequently promised by the Rockefeller Trustees to provide for the payment of a director and an administrative staff charged with the duty of making all necessary preliminary arrangements regarding the building and the scope of its work. Dr. Andrew Balfour was accordingly appointed Director at the end of October, 1923. During the long period that has elapsed since the original decisions were taken we have referred more than once to the great importance of the principles underlying this project, and we therefore welcome the opening of the last stage in the creation of an institution which will, we believe, have a powerful influence on the development of scientific hygiene and preventive medicine in the British Empire and beyond.

#### DESCRIPTION OF BUILDING.

Before proceeding to a description of the building it appears desirable to state very briefly the requirements which had to be met, and which, together with the extent and form of the site and the funds available, determined the architectural form which the School is to assume. The building to be erected has been designed by Mr. P. Morley Harder, F.R.I.B.A., and Mr. Vernon O. Rees, A.R.I.B.A.

Provision had to be made for teaching hygiene in all its branches, for instruction in tropical medicine, and for

research work in both these subjects and in any of the ancillary sciences. The balance had to be maintained equally between teaching and research. Both are essential, both are important, and careful and sympathetic consideration had to be given to both. As a result, it was finally decided to provide for research one-sixth of the total space available for instructional purposes. This may be regarded as a liberal allowance when it is remembered that the space devoted to teaching includes a big lecture theatre, numerous roomy classrooms and general laboratories, a library, a very large museum on two floors, tutorial rooms, and other accommodation. The number of students which the School is intended to accommodate is 250. Of these, it is considered that 100 will be engaged upon the study of tropical medicine—a figure based on the present attendance at the courses given in the Tropical Division at Endsleigh Gardens, where there has of late been an average of nearly seventy each session. The remaining figure, 150, representing students studying for diplomas or degrees in public health, has intentionally been placed very much on the safe side. At present there are only about forty-five students attending courses in London for the diploma in public health, but it is noteworthy that a recovery has taken place from the marked fall in numbers which followed the introduction of the new regulations of the General Medical Council, and there seems little doubt that this increase will continue, although it may be many years before there are as many as 150 aspirants for a public health qualification.

Meanwhile, however, the space provided will not be wasted, for there is likely to be, before very long, a surplus of research workers who can occupy to good effect some of the accommodation for ordinary students. If by the time that more accommodation is required for teaching purposes it becomes necessary to add to the size of the School this could be done, as care has been taken to see that its foundations and walls can carry another story.

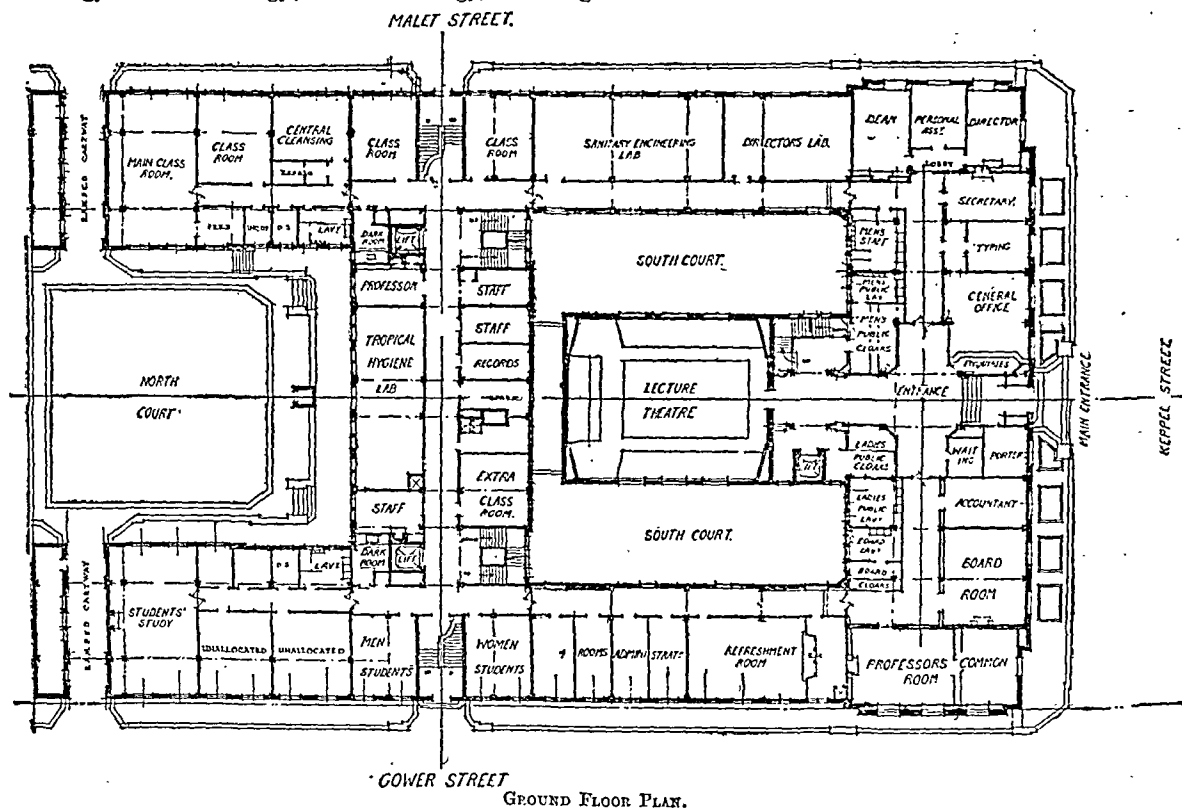

The building—of which the foundations have been laid, while a start has been made upon the steel structure—will be situated between Gower Street and Malet Street, adjoining the large and lofty premises which form Messrs. Bourne and Hollingsworth's hostel. It will front south upon Keppel Street, and it is hoped that at least the frontage, which contains the main entrance, as shown in the illustration, will be of Portland stone. This Keppel Street elevation will be enriched by a wide fringe composed of wreaths and of the names of some of the great pioneers in hygiene and in tropical medicine. Finality has not yet been reached as regards these names. Over the main entrance there will be a large panel on which the handsome and interesting seal of the School will be engraved. There will be side entrances from Gower Street and Malet

Street, with subsidiary entrances to a north court. The elevations to Gower Street and Malet Street will be simple and severe, the only relief to their severity being the emphatic size and projection of the main side entrances. The plainness of the wall surfaces will be somewhat relieved by carving. The general shape of the building is that of a letter H with the Keppel Street front closing one end (the southern end of the H) and the cross-bar dividing the enclosed space into two nearly equal courts, one of which, the northern, is not encroached upon, while the other, the southern, is partly occupied by the lecture theatre. This arrangement provides a building well ventilated and lighted, and it will be easy to find one's way about it, in view of the manner in which the different sections are grouped. The ventilation is by natural means, except in the case of the lecture theatre.

The provisional scheme of studies provided for six main divisions—namely, those of Applied Physics, Physiology, and Principles of Hygiene; Chemistry and Biochemistry; Immunology and Bacteriology; Medical Zoology, including

the "panel system" of heating. This is a modification of the old Roman hypocaust method, and has many advantages, while its disadvantages and difficulties can, it is believed, now be discounted. This, it may be said, is the first occasion where the panel system will be employed for the general warming of a large building of this type; but it is believed that the innovation will justify itself. Accordingly special steel boilers with piping, valves, pumps, and other accessories will be supplied for this purpose.

In the lecture theatre there will be a mechanical system of ventilation, and the fresh air introduced will be steam-heated. There will be an adequate supply of electricity for both light and power. Gas and hot and cold water will be distributed throughout the building, and steam under pressure through the greater part of it. Full inquiries were made as to the desirability of establishing plant for compressed air and vacuum, but it was eventually decided not to do so, partly on the score of expense, and partly because it is now possible to make adequate local provision—that is, in the laboratories themselves—for such services. A dis-

Parasitology and Comparative Pathology; Epidemiology and Statistics; and finally, the Principles and Practice of Preventive Medicine, General Sanitation, and Administration. This grouping has been retained, but, in addition, the fact that the clinical pathology of exotic diseases forms a most important part of tropical medicine has been recognized, and a special laboratory has been devoted to the joint needs of this subject and of certain branches of tropical hygiene, with which, of course, tropical pathology is intimately associated.

#### Basement.

The only true basement is represented by the boiler house, which is wholly below ground level. There the heavy engineering plant will be placed, and, for its domestic hot-water supply, the School will be served by steam-heated boilers (calorifiers), while the boilers supplying the steam will have furnaces designed for burning coke, but capable of easy conversion for oil fuel. A water-softening system will be used in connexion with the boilers for the steam plant.

After long and careful consideration, some experimental trials, and the inspection of premises where the system is in vogue, it has been decided to warm the building by

tilling apparatus and ammonia refrigerating plant will be provided, but, while cold incubator rooms will serve certain of the divisions, others will be supplied with small refrigerators.

The basement, which is really a half-basement, communicates on either flank with useful cellar vaults in Gower Street and Malet Street. On the Malet Street side ten of these will have tiled walls, and will be utilized for the exhibition of working models in connexion with the museum. The basement will be well lit on its outer aspects by windows extending above pavement level and on its inner aspects by windows looking out on the north and south courts. On the Keppel Street front there is extensive provision for museum storage, some of which may eventually be adapted for actual museum exhibits. The storage rooms are flanked on the east side by an x-ray department which will form part of the Division of Applied Physiology, as will the constant temperature room, from which it is separated by the main photographic section. Each division will, in addition, have its own facilities for photographic work. On the west side of the museum storage are situated reserve laboratory storage, the kitchen, dry canteen, and various mess rooms. It is not intended to provide anything more than light luncheons for

the non-professional staff and teas for the staff generally, as there are many good restaurants and tea-rooms in the immediate vicinity of the School.

In the centre, behind the museum storage rooms, is the lower part of the lecture theatre, which has accommodation for 250 students. Behind it again come the lecturers' room and the preparation room. From the latter, cinema, epidiastroscope, and lantern work will be conducted, so that no space will be taken up in the theatre by cumbersome apparatus. Special attention has been paid to the question of acoustics, the elimination of draughts, adequate lighting, and facilities for rendering the theatre dark. The upper part of the boiler house and the engineers' shop are in the rear of the preparation room and lecturers' room.

Library and publication stack rooms are accommodated in the basement, as are large cloak-rooms and lavatories for men and women students. On the east side of the north court is situated a large *post-mortem* room, with an adjoining preparation room. It is hoped here to conduct autopsies upon animals dying in the Zoological Gardens, which often exhibit the lesions of diseases met with in the tropics. At present the School is in close touch with the Zoological Society of London, a member of its staff being pathologist to that society, and it is hoped to make the most of this association. A lobby separates the autopsy room from the laundry.

On the west side of the north court are grouped the goods reception store and issue rooms, together with the carpenters' and metal workers' shops. Elsewhere in the basement are placed the distilling room, the room for large centrifuges, safes for chemicals and valuables, the telephone exchange, and the fans for air extraction. The chamber housing the latter will be insulated to deaden noise.

#### Ground Floor.

The main entrance on Keppel Street will lead into a fine entrance hall, which communicates directly with the stair hall. The latter gives immediate access to the lecture theatre—a convenient arrangement which, on occasions when the theatre is used for "outside" lectures or demonstrations in the evening, or indeed at other times, prevents the audience from wandering about the building and incidentally increasing the work of the cleaning staff. Cloak-room and lavatory accommodation, both for the staff and the general public, are provided at the back of the entrance hall.

The whole of the front block, facing Keppel Street, with the exception of the Gower Street corner, will be used for general administration, the Board Room receiving special architectural treatment, as it will be panelled in oak and ebony. The Gower Street corner houses the professors' common room and writing room. The eastern wing of this floor, facing Malet Street, contains, from south to north, the Director's laboratory and a Laboratory of Sanitary Engineering, which is intended to be partly a classroom, wherein students studying public health will be taught to read and perhaps to prepare plans, will become conversant with the principles of town planning, and will work with rough models of filters and other sanitary appliances with which they should have some acquaintance, if only to enable them to discuss questions of sanitary engineering intelligently with members of the engineering profession. Still further along will come the premises devoted to Division VI—General Sanitation and Public Health—and these extend also into the cross-bar of the H. Ample provision has been made in the way of classrooms, as much of the instruction must perforce be of a theoretical nature, the student getting his practical instruction under medical officers of health and others, both in urban and rural districts.

In the cross-bar facing north, and thus assured of good lighting, is the Laboratory of Tropical Hygiene, already mentioned, wherein the clinical pathology of the tropics will also be taught. It is appropriately flanked by the private laboratory of the clinical pathologist and the room of the lecturer on tropical hygiene. The western wing of the ground floor, facing Gower Street, contains common rooms for the professors and men and women students,

and a room for the service of tea and light refreshments. At the north end is a large students' study room, where silence will be enforced. Elsewhere the accommodation here has been held in reserve until it is found how best it can be utilized.

#### First Floor.

The Library, which will be a large and imposing room 33 feet wide by 120 feet long, is given the place of honour in the front of the building. To its left lie the offices of the Bureau of Hygiene and Tropical Diseases, which it is proposed should continue, as at present, a tenant of the School. It is indeed possible that a closer association will eventually develop. Hence the term "Publications Department" has been inserted in the plans. Behind the offices of this department comes a range of fine large rooms devoted to this important branch of informative and propaganda work. Immediately behind the Library access is provided to the flat roof of the lecture theatre, which will be laid out as a garden court. The west end of the Library is bounded by an ample periodicals room, for it is intended that the current literature shall be separately housed and made readily available for consultation. This room communicates with the Library, and both can be thrown open, together with the above-mentioned roof-garden, on the occasion of large social or scientific gatherings.

A so-called small conference room, which can, however, accommodate over a hundred people, lies to the immediate north of the periodicals room, and to its north again come a spare room and the laboratory for the visiting staff. The rest of this, the west wing, is entirely occupied by the Division of Epidemiology and Statistics, and contains a laboratory, card-index room, study rooms, dark room, and quarters for the staff. The whole of the cross-bar of the H is devoted to the Division of Applied Physiology, as is the northern half of the east wing of the building. This division is likely to be closely concerned with the problems of industrial hygiene, and so, in addition to the x-ray department and constant temperature room in the basement, it is provided with a large cross-lighted laboratory, a range of fine research rooms, mostly facing north, a gas room, and a gas chamber. In one of the research rooms the string galvanometer will find a place. A room has been set aside to serve as a reprint library and for the use of typists, while there are the usual staff quarters, a dark room, a hot incubator room working at 37° C. and 22° C., and a refrigerating chamber or cold incubator room. As in all the large divisions, there is a central cleansing department. Lavatory accommodation for men and women is, as on all the floors, tucked into the angles which the north court makes with the cross-bar of the H.

#### Second Floor.

Here the lower story of the Museum, which will be devoted to hygiene, runs the whole length of the Keppel Street front. In the roof there are three open wells admitting light from above, while it is well lit on the south by windows looking out on Keppel Street, and less fully on the north by

it. There should, however, be it is important to secure as much wall space as possible. The Museum has been granted 15,000 feet of floor space, but in all probability this will eventually be found insufficient to illustrate adequately the huge subjects with which it will be concerned.

The rest of the building on this floor is divided between the Division of Chemistry and Biochemistry and that of Bacteriology and Immunology. The latter has been given the larger share, for there are likely to be more research workers in bacteriology, but there is no great difference in the space allocated to each. Chemistry and Biochemistry are housed in the east wing and eastern portion of the cross-bar of the H; Bacteriology and Immunology are on the western side.

The large laboratory of the Chemical Division in the north-east corner of the building can accommodate 70 students, and the Biochemical and Nutritional laboratory can take 35. It is hoped that special instruction will be given on the subject of nutrition, and that research will be carried out, not only on the nutritional value of

foodstuffs, but on their money value. The best food for the least money is a problem requiring close attention in this and other countries. The biochemist must have his experimental animals alongside him, so a roomy and well ventilated animal house has been sandwiched in between the Biochemical Laboratory and the Museum. Access to it is obtainable from the laboratory. The Chemical Division has its quota of staff and research rooms and a fine classroom with 80 seats. A special balance room takes the place of a refrigerator chamber, but a hot incubator room is provided, as is a dark room. If found advisable, one of the other rooms can be converted into a laboratory for special combustion work.

The chief feature of the Division of Bacteriology and Immunology is the large bacteriological laboratory, which can hold 90 students and has cross lighting and ventilation. There are smaller general laboratories in this division, which also contains a good-sized classroom, media, sterilizing, and washing-up rooms, hot and cold incubator chambers, research laboratories, and the inevitable dark room.

#### *Third Floor.*

The upper story of the Museum, which will be devoted to tropical medicine and hygiene, runs the whole length of the Keppel Street front and has roof lighting, which, as stated, is communicated to the lower story by three open wells in the floor. In close touch with this part of the Museum are the Museum offices and preparation rooms in the west wing. The rest of the floor is wholly given up to the important Division of Medical Biology and will accordingly absorb the greater part of the work of the old London School of Tropical Medicine, now continued at Endsleigh Gardens as the Tropical Division of the present School. Part of the accommodation will be common to the whole division—as, for example, the large laboratory on the Malet Street side with working room for 86 students. This should be a very fine laboratory as, in addition to cross-lighting, it has a weaver roof. Other rooms which will be shared by the four departments constituting this division are the two large classrooms, the preparation room, the seminar room, the advanced demonstration room, the reading and reprint room, and the insectarium and aquarium.

In the advanced demonstration room, as in the tropical hygiene laboratory on the ground floor, there will be sliding partitions so that the room can be turned at will into working cubicles or used for general demonstration purposes. The rest of the space—that is, that between Malet Street and the north court and that between Gower Street and the north court—is more or less equally distributed between the Departments of Helminthology, Comparative Pathology, Protozoology, and Entomology, and is represented by staff rooms, preparation rooms, hot incubator rooms, and so forth. There are some special features, such as a joint dissecting room for helminthology and comparative pathology, a room for housing the helminthological collections, a faeces room, adequately ventilated, and a stock room for entomological specimens. There is, fortunately or unfortunately, one spare room in this division, and it is to be hoped it will not prove an apple of discord.

#### *Fourth Floor.*

This is a recessed floor occupying only the cross-bar of the H and the southern portion of the Gower Street front. Towards Malet Street lie the caretaker's quarters, towards Gower Street the artist's room and cinema preparation room. Between stretches part of the animal quarters, with exercise court and all conveniences. From the artist's room there runs south a special range of mice quarters. A separate heating plant will be provided for the animal quarters. A raised sloping area on the Malet Street side of the roof of the third floor will be covered with slates and will be used for the collection of rain water, which, after being filtered in a special way, will be led by pipes to the aquarium.

#### *Fifth Floor.*

This is represented by additional accommodation for animals and provision for water tanks and fan chambers. Like the fourth floor, it is recessed from the wall line of the main building and is of no great extent.

#### LAYING OF THE FOUNDATION STONE.

Sir ALFRED MOND, Bt., M.P., Chairman of the Board of Management, recounted the circumstances of the Rockefeller benefaction, and then went on to describe the building as a workshop where skilled labourers would pursue their tasks for the betterment of the human race. The simple dignity of the frontage was a key to the fundamental purposes of the school. After announcing that the Board of Management had made representations to the Senate of the University of London for the appointment of professors to two of the new chairs, he paid a high tribute to the assistance afforded by Sir Cooper Perry, whose impending retirement from the principalship of the university happily did not involve the severance of his connexion with the school, for he was vice-chairman of the Board of Management.

The Hon. W. G. A. ORMSBY-GORE then spoke on the relation of the work of the tropical division of the school to the dominions and colonies. Ever since he had been at the Colonial Office it had appeared to him that British trusteeship for the great tropical possessions made it necessary to be up and doing in the matter of health and sanitation. Britain had all round the world a belt of tropical possessions, and from all those which he had visited, alike in East and West Africa, he had come away with the idea that, both from the point of view of the welfare of British officials and traders, and from that of the native populations, there was a great task ahead. At present the mortality and sickness rates in many areas were appalling. He paid a tribute to two great men, to whom the building would be in some sense a monument—namely, Mr. Joseph Chamberlain and Sir Patrick Manson. Only those who had visited the tropical empire realized the debt which humanity owed to Manson, whose example and tradition would be perpetuated in the school.

The Right Hon. NEVILLE CHAMBERLAIN (Minister of Health), before laying the stone, said that the ceremony marked the commencement of a building in which the two great English-speaking nations shared. To him also it was a great gratification, within a few days of the ninetieth anniversary of his father's birth, to add another stone to the fabric which Joseph Chamberlain founded in 1899. The linking up of the London School of Tropical Medicine with the wider field of preventive medicine was a recognition of the fact that, whilst the study of tropical diseases was still, and probably must always be, the work of the specialist, it formed only a branch of the much wider application of a science covering every clime and every people. Sir Cooper Perry had called his attention to the need of the school for further permanent hospital facilities, and he hoped shortly to appoint a committee (of which Sir Alfred Mond had kindly consented to act as chairman) to go into that matter. Mr. Chamberlain then gave a brief history of the school and what it owed to the Rockefeller Foundation. He touched also upon some of the principal departments of the work—the study of physiology as applied to hygiene, of bacteriology and immunology, of medical biology, of epidemiology and vital statistics, and, finally, sanitary science and public health in general.

Mr. Chamberlain then laid the stone, after which Dr. Andrew Balfour, director of the school, handed to him and to Mr. Ormsby-Gore replicas in silver of the school seal. A telegram was sent to the Rockefeller trustees, conveying the Minister's cordial greetings, and adding that, "The British and American flags fly side by side at the dawn of a new era of preventive medicine."

Among those present at the ceremony were:

Sir Humphry Rolleston, Bt., Sir John Bland-Sutton, Bt., Sir George Newman, Sir Cooper Perry, Sir Holburt Waring, Sir Walter Fletcher, Sir Leslie Mackenzie (Scottish Board of Health), Sir John Robertson (Birmingham), Sir Arthur Robinson (Ministry of Health), Sir Malcolm Delevingne (Home Office). The British Medical Association was represented by Dr. H. B. Brackenbury (Chairman of Representative Body), Mr. Bishop Harman (Treasurer), and Dr. Alfred Cox (Medical Secretary).

Previous to the stone-laying, Sir Alfred Mond entertained a large party to luncheon at the Carlton Hotel.

## MALARIA RESEARCH IN ENGLAND.

WE have before us the Report on the First Results of Laboratory Work on Malaria in England,<sup>1</sup> by Colonel S. P. James and Mr. P. G. Shute. If this *hors d'œuvre* is an earnest of the feast of good things to follow we must look forward to a period of serious mental digestion; the food for thought provided is ample in quantity and rich in quality. The account given helps considerably to elucidate certain points which are obscure in the epidemiology of malaria, and opens up new views of the directions in which anti-malarial measures should be undertaken.

The employment of infected mosquitos in the treatment of general paralysis to overcome the objection to direct inoculation of blood from patient to patient has afforded an excellent opportunity of studying malaria contracted in a natural way and the conditions and circumstances governing infection of mosquitos. Pure strains of the benign tertian parasite were used, and *Anopheles maculipennis* as the vector. Of 2,630 female mosquitos used 530 were found ultimately available for infection of 145 patients, of whom 109 developed the disease. It was found that the mortality of *A. maculipennis* kept in artificial "tropical" conditions at 24° C. was high—about 50 per cent. during each seven to ten days of life. At 22° C. it was less, but the time taken to become infected was longer, and fresh feeds of blood were needed daily or every other day. If a temperature of 26° C. was maintained with a view to obtaining quick infection nearly all the mosquitos died before the salivary glands contained sporozoites—that is, before they became infective. At a low temperature, such as 4° to 6° C., infected mosquitos lived up to two and a half months and retained their infectivity. These facts may help to explain the absence of new cases during very hot seasons, and also, since the oöcysts are arrested in development but not killed by the low temperatures, the recrudescence of cases in the spring.

The authors found, further, that a surprisingly small number of persons who suffer from malaria are infective to anopheles. Some with induced malaria were not infective at any period of their course, and the strikingly infective patient was a rarity, while repeated feeds on an infected patient were needed to infect the mosquito. Since this occurred under the most favourable artificial conditions it is thought probable that "95 per cent. of potential malaria-carrying mosquitos will never play that role." Hence, it is concluded, much of what is done in the way of antimalarial measures is wasted effort.

Further, it would appear that malaria is a disease which does not spread unless a number of special conditions are fulfilled, and is probably to a large extent a "household" disease, and should consequently be dealt with in the houses of the people as much as, in fact more than, in their environment.

Interesting results were obtained relative to what has been erroneously termed "immunity to inoculation." Great caution must be exercised to avoid confusing immunity with diminished susceptibility or

increased resistance to infection, because patients differ much in this respect. It is suggested that this difference may perhaps be ascribable to some simple cause, such as modifications in the blood as regards alkalinity, or a change in the content of lecithin or other bodies, and not to the presence of "immune bodies" in the blood.

The clinical observations are also of vast importance in showing that the classical description of benign tertian malaria cannot stand in the case of the induced disease. The course is divisible into three stages. In the initial stage, lasting for two to five days, there was gradually increasing irregular fever, remittent in character at first, later intermittent, but without any rigors. In the second, or developed, stage, in 80 per cent. of cases there was for ten days or more a quotidian fever with daily rigor, even if infection had been conveyed by a single bite. The third, or terminal, stage was characterized by the type of fever changing from the quotidian to the tertian. The incubation period was usually twelve days, but in many it was ten days; it might be as short as seven or as long as twenty-three. The parasites were not as a rule found in the peripheral blood till the second or third day of fever. In a second attack from a new infection, even after a prolonged interval, the temperature was of the true tertian periodicity. If, therefore, a patient showed a typical tertian temperature from the start, this very fact was a strong indication for inquiry as to a history of previous malarial attacks.

In the treatment of general paralysis it was found that a rigor on alternate days was followed by greater benefit than when a rigor occurred daily. This objective was usually attained by allowing the primary attack to continue for four or five days, then giving a small dose of three to five grains of quinine to bring about a temporary check, and waiting for a relapse. Under these conditions the temperature was nearly always of the true tertian character, with rigors on alternate days.

Future reports will be awaited with keen anticipation.

## ORTHOPAEDIC CENTRES FOR WALES.

SIR ROBERT JONES, whose energy and enthusiasm led to so much being done for the soldier crippled in war, has not ceased to direct attention to the needs of crippled children. On July 1st he delivered an address at a meeting arranged in London (at Carnegie House) by Sir John Lynn-Thomas, who will act as honorary secretary of the Welsh Branch of the Central Committee for the Care of Cripples then inaugurated. Lord Kenyon presided, and many medical officers of health and others from Wales were present. A message was read from the Prince of Wales in the course of which he expressed a hope that an alliance might be made with the hospital in Cardiff which bears his name (the Prince of Wales's Hospital for Limbless and Crippled Soldiers). Sir Robert Jones said that crippled children were in exactly the same position as the soldier who had suffered damage to his limbs in warfare. The child must be seen early, and it must have rest at the onset of the disease. To meet these requirements there must be plenty of hospital beds so that there might be no waiting list, rapid evacuation must be avoided, and there must be provision for after-care in order to secure continuity of treatment. To achieve this ideal treatment three things were essential—open-air hospitals, skilled staffs (medical and

<sup>1</sup> Report on the First Results of Laboratory Work on Malaria in England. By S. P. James, M.D., (ret.), assisted by P. G. Shute, Laboratory Assis. Publications of the League of Nations—III, No. 1, 1925.

nursing), and after-care clinics. The hospital must be in the country; the staffs must be specially trained; the hospital must be thoroughly equipped for physiotherapy, and with ultra-violet rays, and so on. The after-care clinics should be within twenty miles of the hospital. Such schemes were already in existence in Oxfordshire and Shropshire; Wales was a difficult problem; but it was well to remember that it had a well organized tuberculosis scheme. Although the charter of the Welsh Memorial Association did not allow non-tuberculous cripples to be brought under the same control as the tuberculous, Sir Robert Jones hoped that both sides would come together for the purpose of distributing crippled patients to appropriate hospitals, and that they might arrange to divide certain expenses between them. Schemes might be started in one of two ways—either mainly by voluntary effort with State aid (a method which Sir Robert seemed to favour) or as a municipal scheme. He urged that Wales should get to work as soon as possible, that the centres already in existence at Cardiff and at Gobowen, near Oswestry, which was also serving some of the eastern counties of the principality, should be developed, and a third centre established in Bangor for Northern Wales. Meanwhile the headquarters should be at Cardiff, an admirable centre for a start because of the existence of the Welsh National Medical School. Cardiff would need an open-air hospital of at least 100 beds in addition to the Prince of Wales's Hospital. There should be clinics in various centres, the localities to be determined after careful consideration. In their establishment and supervision the help of Miss (now Dame) Agnes Hunt should, if she were willing to give it, be obtained. A body of whole-time orthopaedic nurses, fully trained if possible, should be got together and a skilled medical staff appointed. Provision should be made also for the treatment of adult cripples. Sir Robert Jones called particular attention to the need for full fellowship and accord with the local medical practitioners, who must always be the first line of defence. As a first step in starting a scheme, a meeting should be called by local committees to which the doctors and the chief people of the neighbourhood should be invited; and school doctors, medical officers of health, and general practitioners should always be welcomed at the hospitals. An advisory board for the selection of sites would be a great advantage.

It is probable that the medical profession will agree that such schemes as Sir Robert Jones outlined should have a voluntary basis, although it may not be possible entirely to do without the aid of the State or the County Councils. The health and education authorities are now so much concerned with the welfare of the patients who come under these schemes of treatment that it is only natural that payments by these authorities should form a large item in the hospital receipts. Thus, in the financial statement of the Wingfield Orthopaedic Hospital, near Oxford, of which Mr. Girdlestone is clinical director, it appears that receipts on account of services to patients, presumably paid chiefly by local authorities, amounted to £18,000 out of an income of £21,000. But the hospital remains a voluntary hospital with a voluntary staff, and with a committee which includes a large number of voluntary members. Many of the members represent other voluntary hospitals and voluntary bodies, such as the British Red Cross Society, while local authorities are represented by members appointed by the county councils and boroughs. The after-care clinics have energetic local ladies as honorary secretaries; the funds are raised locally through subscriptions, entertain-

ments, and patients' payments. A scheme such as this appears to retain as far as possible under modern conditions the voluntary principle; probably the principle has advantages in economy, possibly in efficiency, and certainly in freedom and sympathy, over less flexible schemes administered by public authorities.

There can be little doubt that early experiments in organization are best conducted by private effort, especially under existing economic conditions; and the reference made to Sir Robert Jones's enthusiasm by one of the proposers of the vote of thanks sufficiently indicated the damping effect of the official mind when it is a matter of balancing the enthusiasm of the pioneer against the care of the public purse. At the same time the ultimate cost of public administration almost invariably tends to become excessive.

A cordial vote of thanks was accorded to Lord Kenyon for presiding, to Sir Robert Jones for his address, and to Sir John Lynn-Thomas, the honorary secretary of the new Welsh branch, to whose enthusiasm the inauguration of the branch is largely due.

### ST. KILDA.

To many of us the name of St. Kilda raises up only recollections of Boswell and of Dr. Johnson's speculations in epidemiology, but the island is interesting from a medical point of view on account of the former terrible mortality among newborn children therein and the occurrence of what is known as boat-cough. In former numbers of this JOURNAL these subjects have been discussed, and full accounts of the place and its inhabitants have appeared from time to time.<sup>1</sup> Situated in the Atlantic some sixty miles to the westward of the greater Hebridean islands, the St. Kildeans have until lately been in the world but hardly of it, for throughout the winter months the island is inaccessible. No doubt the popularization of wireless communication will, if it has not already done so, much modify their isolation. In 1912 a trawler brought the news to Aberdeen that the islanders were starving. The Admiralty at once ordered a warship to call and relieve their most pressing wants, and a London daily paper, scenting a "scoop," chartered a steamer and engaged a surgeon and others to take food and necessaries to them. No time was lost, but when they arrived at St. Kilda the journalists found that H.M.S. *Achilles* had been before them, and that there was no starvation or distress to be relieved. A full and interesting account of the island and its people, as they then were, appeared in this JOURNAL soon afterwards (1912, i, 1249) from the pen of the surgeon in question, Dr. C. J. Gordon Taylor.

Starvation has not in the past been a great danger to the islanders, who rely chiefly on a plentiful supply of seabirds for their food, but slow extinction threatened them in the last century through the excessive infantile mortality from tetanus or trismus nascentium. Dr. John E. Morgan stated<sup>2</sup> that in the ten years 1830 to 1840 there were 65 births and 64 deaths, of which 33 deaths at least were due to the "eight-day sickness." The population amounted to 105 in 1830, but it has since declined to about 80, at which figure it appears to be stationary. The people are strong and healthy despite their necessarily consanguineous marriages; they are not subject to dangerous epidemics, and but for a few casualties incidental to rock-climbing in the taking of seabirds they run few risks.

<sup>1</sup> BRITISH MEDICAL JOURNAL, 1895, ii, p. 160; 1912, i, pp. 1201 and 1259.

<sup>2</sup> BRITISH AND FOREIGN MEDICO-CHIRURGICAL REVIEW, January, 1852, p. 176.

More than thirty years ago Dr. G. A. Turner, in his presidential address to the Glasgow Obstetrical and Gynecological Society,<sup>3</sup> told how the infantile mortality from tetanus was done away with. The owners of the island had done their best, and a Gaelic-speaking nurse from Glasgow had spent some months in St. Kilda, during which the babes of whom she had charge survived, but after she left no successor could be found. Then the minister, the Rev. Angus Fiddes, stepped into the breach. He took a course of training under Dr. Turner, and returned to St. Kilda to assume the duties of monthly nurse. He seems to have rather misunderstood some of his instructions, for he nearly starved the newborn infants, and stupefied them with two grains of chloral daily; but despite this, cleanliness and iodoform won the day. Since 1891 no deaths from trismus nascentium have occurred.

Before the discovery of the tetanus bacillus there were many speculations as to the cause of trismus nascentium. It is interesting to note that in 1846 Marion Sims attributed it to displacement of the cranial bones, especially the occipital, a pathology which seems to have been favoured by earlier writers, for Quincy in the eighteenth century stated that overlapping of these bones caused convulsions and death. The discovery of the bacillus does not seem even yet to have set the question at rest. It has only altered it, so that now the problem is to find how the organism reaches the umbilical cord from the soil or some other breeding place.

In a recent most interesting article on "The tragedy of St. Kilda"<sup>4</sup> Dr. G. Gibson of the General Board of Control, Scotland, suggests that probably the umbilical cord was dressed with fulmar oil, and that this contained the specific organism. The fulmar petrel (sometimes wrongly called a gull) is almost the staff of life to the St. Kildians. It furnishes a large part of their diet, some 150 to 200 being salted annually per head of the population for winter use. It is not a pleasant creature. Known to whalers and fishermen as "the greedy molly-mawk," and alluded to by Dr. Gibson as a "winged skunk," it suggests the midshipman's characterization of certain savages, for it has "no manners and its customs are beastly." One of these is when annoyed to squirt some of the oily contents of its stomach into the intruder's face. This habit is taken advantage of by the islanders, who dexterously divert the oil into a receptacle, such as the dried stomach of a gannet, in which they store it for use. Dr. Gibson does not attempt to prove that one use of the oil was as a dressing for the umbilicus, nor, further, that it usually contains living tetanus bacilli; and we think that until he has made such demonstrations his suggestion must remain no more than an ingenious speculation. It is to be remembered that trismus has been a scourge of lying-in hospitals and other places where fulmar oil is unknown. Not only in the islands near Iceland, but in such places as Demerara and Dublin, it has caused shocking mortality. In the beginning of the nineteenth century 18 per cent. of the children born in the Rotunda Hospital died of trismus, as was pointed out by Dr. C. R. Macdonald in 1886 in considering this question in our columns.<sup>5</sup> There are doubtless many ways by which the bacillus might be conveyed to the umbilical cord, but until its presence is proved in the stored fulmar oil it is unnecessary to inquire whether that oil was formerly used as an unguent for the navel.

The "boat-cough" from which the St. Kildians suffer after they are visited by strangers seems to be a febrile catarrh, and is no doubt analogous to the "shore-cough" to which in the old sailing-ship days seamen so often fell victims when they first landed from long sea voyages. When the Dreadnought Seamen's Hospital Society maintained an out-patient dispensary in Well Street, London Docks, a large share of the medical officer's time was devoted to the treatment of such catarrhs. A similar course of events has been noticed in children's hospitals where some of the patients spent their whole time in the open air. When brought into a ward for operation or some other purpose these children commonly suffered from catarrh, from which they had been free while outside.

#### THE PRESERVATION OF THE EYESIGHT OF CHILDREN.

THE letter of Dr. W. Oliver Lodge of Bradford (p. 93) opens up a large field for consideration. He rightly points out that there are many defects of eyesight which are discovered too late for the effective prevention of serious consequences. The conditions which give rise to these defects, or the defects themselves, may be present in early infancy, and certainly exist when the children come first to the elementary schools. Defects arising from cataract are generally recognized early, often by the parents; squint is such an obvious deformity that it calls for immediate attention in every civilized community, and it certainly gets it at least as soon as the child goes to school. But there are other defects—high degrees of astigmatism, early myopia, and suchlike errors of refraction—which may not give obvious notice of their presence. These, Dr. Lodge claims, should be discovered by the systematic examination of infants' eyes so soon as they go to school, and their discovery should not await the age of 7 years, when the first routine examination of physique, including vision, is undertaken by the school medical officers. That there is a large amount of undiscovered defective vision in the infant schools is certain. In a discussion held by the Ophthalmological Society in 1919 papers were read by Dr. James Kerr, Dr. William Sym, and Mr. Bishop Harman in which this subject was dealt with. The last named gave the findings of the routine examination of the eyes (with an efficient cycloplegic) of all the infants, to the number of 368, in a good class London elementary school within the ages of 4 and 7 years. Allowing a liberal error of refraction as within the "average," he found that no less than 35 per cent. had such high errors of refraction that medical attention and some form of easement of the educational regime was undoubtedly necessary. The most obvious medical treatment would be the provision of spectacles to correct the errors of refraction. But such a proposition opens up a wide question as to practicability. Would the most enthusiastic desire to see one-third of the infants wearing glasses? And if the infants had the glasses, how long would they remain in effective use? Besides, there is the large question of expense—both that involved in the necessary medical examination of large numbers of infants, and the cost of providing and replacing spectacles. It would appear that the necessities of such a situation would be far better met by making the education of infants meet for the infants rather than to attempt to make the infants able to undertake some educational regime, a scheme possibly evolved apart from consideration of the tenderness of the eyes of infants, be they "average" or worse than average. The opening phases of infant education are as difficult and need as much care and thought as the polishing of the finest minds of the public school or the university;

<sup>3</sup> *Glasgow Medical Journal*, March, 1895.

<sup>4</sup> *Caledonian Medical Journal*, vol. xiii, No. 2, April, 1926, p. 50.

<sup>5</sup> *BRITISH MEDICAL JOURNAL*, July 24th, 1886, p. 160.

indeed, the risks involved in infant education are the greater, for the younger the subject the smaller the power of resistance, and lack of care may give an unhappy twist to budding mind and body which may be irrecoverable. But, apart from this, there is much to commend added attention to the eyesight of the infants in our elementary schools.

#### PUBLIC HEALTH IN CHINA.

In a nation with wide-flung empire, such as ours, it is perhaps not easy to arouse interest in the health activities of a foreign country so distant as China. Nevertheless, our trade interests in Eastern Asia are very great; the health of the workers employed by British merchants is of importance; and the functions of such bodies as the Manchurian plague prevention service and of the sanitary bureau which controls maritime quarantine have international aspects. There is now arising in China a body of cultured medical opinion, trained abroad, which desires to improve the sanitary condition of the country, and to establish a public health service modelled largely on that of England. For promoting this object an Association for the Advancement of Public Health in China has been formed; and the association has addressed a memorandum to the British Boxer Indemnity Commission. As the Boxer rising in 1900 is probably hardly remembered now, it may be recalled that China is paying an indemnity to the Western nations which took part in the suppression of the trouble, and that portions of that indemnity are being used by some of those nations to assist in the development of China. Hitherto the British have applied these funds largely to education; but the trouble stirred up by Chinese students last year led the Government to send out a commission under Lord Willingdon to inquire on the spot as to the best direction in which to apply the indemnity. It was to this commission that the Association for the Advancement of Public Health in China presented its memorandum, which, if sometimes stiff in expression and over-elaborated, is written in very good English. It appears that in China a certain amount of machinery exists for public health purposes, but it is unorganized and mainly in the hands of the police. A sanitary service with skilled medical directors and a personnel of sanitary inspectors does not exist. The Chinese doctors, in their memorandum, ask that a portion of the Boxer indemnity, previously devoted to education, should now be applied to what they call "demonstrations" for a period not exceeding five years, and to the training of a sanitary personnel. By "demonstration" they appear to mean that a city should be selected as a centre and should be used experimentally as a sanitary area, with the approval and assistance of its local authority. The association suggests three such centres—one in Peking, one south of the Yangtze, and one in Szechuan. In these areas, it suggests, experiments should be made in the introduction of public health measures. The "demonstrations" should cover administration, vital statistics, communicable disease, and general sanitation; the personnel should be trained locally in connexion with the work of each area. The diseases against which the health work should be specially directed would be tuberculosis, small-pox, plague, cholera, and the gastrointestinal diseases due to soil pollution. It is stated in the memorandum that the present lack of stability in government in China affects only the national and provincial governments, and that the initiation of successful public health work depends upon the local governments, which are unaffected. In an appendix to the memorandum an account is given of the lamentable condition under which the Chinese labourer lives, with horrible descriptions of the bad housing and feeding and lack of medical attention and nursing found in some of the places visited. The

memorandum ends with an appeal to the British Boxer Indemnity Commission to help to deliver the workers from their misery, and thus to stop the progress of Bolshevism. It should be a source of satisfaction that distinguished members of the National Medical Association in China should turn to this country for help in preventive medicine. Great Britain, they say, was foremost to recognize the importance of public health, and modern industrialism originated in Great Britain. Their proposal seems to merit serious consideration by the Foreign Office and the Government.

#### PROPOSED POST-GRADUATE HOSTEL IN LONDON.

THERE has long been a feeling that medical men who come to London for post-graduate study have no opportunity of meeting their teachers and fellow students socially. This was one of the original aims of the Fellowship of Medicine, established by Sir StClair Thomson and the late Sir John MacAlister as an organization independent of the Post-Graduate Association. For various reasons, including financial considerations, the Fellowship did not make all the progress that was desired, and after a short experience strengthened its position by amalgamating with the Post-Graduate Association. Many of those who have given attention to the organization of post-graduate medical education in London believe that there is need for a special hostel in London at which graduates taking the courses now arranged by the combined Fellowship of Medicine and Post-Graduate Association could reside. It will be remembered that rather less than a year ago the Minister of Health appointed a committee "to draw up a practical scheme of post-graduate medical education centred in London," and, although we have no direct information, it is probable that one of the subjects which will be discussed by that committee will be the establishment of such a hostel. Meanwhile, in order to test the extent of the need, arrangements have been made to provide a central place of residence for post-graduate students where they will be received at rates varying with the requirements of the visitor. The hostel will be under the supervision of a president, a director, and a treasurer, who will form the committee, working in conjunction with a board of vice-presidents drawn from the metropolitan and provincial schools and three or more members chosen by the post-graduate members themselves. The suggestion was brought before the Council of the British Medical Association at its last meeting, and the Medical Secretary was appointed to take part in the preliminary arrangements and to assist in giving the scheme a start. The managers of the Imperial Hotel in Russell Square have agreed to place at the disposal of the committee a bedroom with writing table for each member; a reading room which will be available all day and every day; a dining room where breakfast and dinner can be taken apart from the general guests of the hotel; and a lecture room which is to be at the service of the hostel from 9 p.m. every day. It is hoped that the members of the committee will take frequent opportunities of dining at the hostel, and that after dinner informal discussions may take place on subjects of medical interest. A preliminary meeting was held on Tuesday last, when Sir D'Arcy Power, K.B.E., F.R.C.S., took the chair and explained the objects of the hostel as set forth above. He expressed the hope that it would be found possible to work with and by the Fellowship of Medicine, which was doing such excellent work in post-graduate teaching. He attributed the inception and carrying out of the scheme to Mr. A. P. Bertwistle, F.R.C.S.Ed., formerly of Leeds and now of London, and read a number of letters of approval from leading members of the profession. Further particulars may be obtained from Mr. Bertwistle, 4, Spital Square, Bishopsgate, E.1.

## OPEN-AIR LIFE IN WINTER.

EXPOSURE to cold increases basal metabolism. Hence, in part at least, the sense of well-being induced in the physically fit by outdoor sports. Hence, too, in part at least, the usefulness of the open air in the treatment of the sick. Its value to those who come between these two classes, being neither wholly fit nor yet actually diseased, is well shown in a recent report by Dr. S. G. Moore, medical officer of health for Huddersfield. In it he summarizes in an interesting way the effects of treating 62 sub-par Huddersfield children, aged from 5 to 13 years, for periods between October 17th, 1925, and March 29th, 1926, at a residential open-air school, the Cinderella Holiday Home at Honley. Clothing suitable to withstand the winter cold was provided, but no medical treatment was given. Artificial sunlight was started in some cases, but was discontinued after four days owing to an outbreak of scarlet fever in the home. A number of the children for various reasons went out of residence, but it was possible to make serial observations on 39 (20 boys for sixty-six days and 19 girls for eighty-two days). All these on admission were anaemic, debilitated, and mentally dull. They soon became bright, alert, and full of vitality. All, with a few exceptions, showed increased chest expansion on discharge. The increase in weight of both boys and girls during the periods of treatment, calculated for age groups on an annual basis, was greatly above the corresponding annual figure for the average Huddersfield child of the same age. On the other hand, the increase in height, similarly worked out, was in boys below the Huddersfield average, though in some of the girls it was above it. For the boys the average percentage of haemoglobin on admission was 76.8, on discharge 82.8; for the girls—on admission 77.37, on discharge 83.37. Both sexes had an increase of 6 per cent., but both were still below the normal 87 per cent. for children. For the boys the average red cell count on admission was 4,672,625, on discharge 4,760,800; for the girls—on admission 4,512,631, on discharge 4,985,263. The increase for girls was greater than for boys, but both sexes still fell short of 5,500,000, the normal count for children. Enlarged glands, if present, were in all cases cured or improved, and enlarged veins of the trunk in all cases but one. It is clear from Dr. Moore's account that these children derived much physical and mental good from their winter life at Honley. Their increased chest expansion and the disappearance of enlarged trunk veins suggest gain in respiratory capacity. Their disproportionate rise in weight is evidence alike of their initial disability and of the extent to which it was redressed. As the daily average of bright sunshine in the neighbourhood of Honley during the six winter months is under two and a half hours, it may be surmised that keen fresh air and good food and clothing were the principal factors in producing these results.

## FOOD PRESERVATIVES.

THE control of the use of preservatives in food still rightly excites a great deal of interest both among the medical profession and the public. The new proposals are strongly opposed by certain members of the trade, and upon a matter of this kind the opinion of Professor E. Mellanby, F.R.S., of Sheffield, is most valuable. We may therefore recall some of the arguments used by him in an address he gave last autumn to the National Council for Domestic Studies. He divided food preservatives into three classes: (1) formaldehyde and hydrofluoric acid and their derivatives; (2) boron preservatives and salicylic acid and its salts; (3) benzoic acid and sulphurous acid and their salts. All these substances, he said, were toxic to some people in certain doses, and, while they prevented putrefaction, none of them were completely protective against organisms of the salmonella group and their toxins, which are respon-

sible for many outbreaks of food poisoning. On this point Professor Mellanby expressed the opinion that there was a double danger in food preservatives: first, that they prevented the hoisting of the danger signal of putrefaction; secondly, that they failed to inhibit with equal efficiency the growth of the more common food poisoning micro-organisms. Of the two departmental committees appointed to consider food preservatives, that which sat from 1889 to 1901 brought about the rejection of the first group of preservatives, formaldehyde and hydrofluoric acid. The departmental committee of the Ministry of Health, appointed in 1923, recommended the rejection of the second group, the boron preservatives, so that after 1927 the only preservatives allowed should be benzoic and sulphurous acids and their salts. Boric acid and other substances of the group were, he said, very popular with manufacturers, probably because they were tasteless, odourless, and, when added in quite a small proportion, delayed putrefaction, although they did not prevent to the same degree the development of the Gaertner bacilli. From the commercial point of view, boric acid was better than common salt for preserving meat; it did not withdraw the water or spoil the shape, nor did it produce discoloration, and the meat was less stringy and tough. Boric acid was used, however, in so many foods that many people were taking comparatively large quantities daily, probably from 8 to 30 or even 40 grains. There was no doubt of the toxicity of boric acid in large quantities, and even in small quantities in susceptible people. The drug could produce nephritis in animals, so that it was possible that boric acid might be one of the causes of Bright's disease in normal individuals. No doubt many people lived to a hearty old age in spite of consuming boron preservatives; but Professor Mellanby thought it probable that the drugs might cause some disturbance of health, evidenced by dyspepsia, rashes, and possibly renal disease. Coming to the third group, Professor Mellanby observed that benzoic acid was rapidly excreted as hippuric acid, and that sulphurous acid was converted to a sulphate, and so merely formed part of what many people took daily as a purgative. Nevertheless, he argued for the prohibition of the use of all preservatives, and believed that later on another committee would sit and the third group would go. Transport and cold storage would improve greatly, and the need for chemical preservatives would be as little necessary in England as it was now in the United States. One argument used by Professor Mellanby was that as all these substances prevented the reproduction and growth of bacilli they were likely to have a detrimental effect on human beings, who were made of the same material as bacilli. If they were poisonous in large quantities, it was only safe to believe that they were harmful to health in smaller quantities, especially when taken continuously. Benzoic acid, although it could be taken with a certain amount of impunity up to 8 grains a day, would cause death if taken in large quantity; and there was no doubt that sulphites acted as gastric irritants. Again, if the same foodstuff from one source was in some cases adulterated with preservatives and in others unadulterated, it was plain that it could not be claimed that preservation was essential. None of the butter from New Zealand and Australia imported into the United States was allowed to contain preservatives; yet some of the butter imported from the same sources into this country was preserved. Finally, Professor Mellanby pointed out that during the last forty years, coincident with the use of food preservatives, there had been a development of a number of diseases, the colossal importance of which the average layman did not grasp. Cancer, of which so much was heard, was unimportant from an economic standpoint compared with many other diseases to which we were liable. Of these, diseases of the alimentary canal were pre-eminent. The mortality from intestinal diseases had greatly increased in recent years. Thus,

between 1880 and 1919 deaths in quinquennial periods at Guy's Hospital due to peritonitis had increased progressively from 176 to 285; those from gastric ulcer from 0 to 83; from duodenal ulcer from 0 to 38; and from appendicitis from 9 to 91. These increases were the more serious since the standard of food and hygiene had improved greatly during those years, while abdominal surgery had advanced beyond all estimates. If food preservatives were not connected with this serious state of affairs, it was strange that the development of the two things should coincide.

#### VENTILATION AND HEATING IN FACTORIES.

THE Industrial Fatigue Research Board has issued a report by Dr. H. M. Vernon and Mr. T. Bedford, assisted by Mr. C. G. Warner, entitled "A physiological study of the ventilation and heating in certain factories." Up to recently the investigation of the effect of atmospheric conditions on efficiency and fatigue has been confined to industries in which the atmospheric conditions have been rendered to some extent abnormal, either through the heat produced in manufacture or owing to the technical requirements of the process. In 1923 the Research Board decided to investigate the physiological aspects of ventilation generally. The first report, which was published recently (by H. M. Vernon and others, 1926: "Methods of investigating ventilation and its effects"), dealt with the theoretical side of the problem. The present report contains the results obtained under practical conditions, and has a more direct industrial interest. The authors state that the work of Dr. Leonard Hill has shown that it is not usually the chemical purity of the air in a room that needs investigation, but rather the adequacy of the degree of air movement and the suitability of temperature. The requirements in a workroom are as much air movement as possible without "draughts," and an atmosphere which keeps the head relatively cool and the feet relatively warm. Generally speaking, the air should move in an upward direction. Where possible a natural system of ventilation is preferable to any artificial system. The authors had an opportunity of testing a system of natural ventilation combined with occasional artificial ventilation in a newly built boot and shoe factory at Kettering; and a large part of their experimental work was conducted in this factory. The hot-wire anemometer, the thermopile, and the kata-thermometer were among the instruments used in the experiments. The conclusions are summarized at the end of the report. The investigators are thoroughly in favour of employing natural, as against artificial, systems of ventilation, though they realize that it may be frequently impossible to avoid artificial aids. Natural systems are less expensive, more pleasant, and more healthy. In winter cross-window ventilation is often insufficient, so that some form of exhaust is necessary. The extraction of air should never, in ordinary circumstances, be at floor level, as this increases air movement round the feet of the workers. The investigators favour a height of seven to eight feet above the floor for air extraction, as this increases air movement at the head level of the workers. If natural window ventilation, coupled with moderate fan exhaust, cannot be applied satisfactorily, ventilation must be induced by mechanical means. A plenum system is satisfactory if the hot air is discharged at floor level and not overhead. In dusty processes of manufacture, when floor discharge would be inadmissible, the ducts might be made to discharge against horizontal deflectors a few inches above the floor. The openings of the ducts should not be more than six inches in diameter, in order to avoid draughts. The authors lay the greatest stress on starting the source of heat as near the floor as possible, or under the floor, and keeping the hot air or

radiators at a relatively low temperature, in order to avoid a large temperature gradient in the heat of the workroom. In this respect Dr. Vernon and his colleagues cannot sufficiently condemn overhead steam pipes, except when some overhead piping is required for checking down draughts of air from skylights.

#### "THE CANCER REVIEW."

WITH a view to increasing the co-operation between clinicians and scientists who are engaged in any form of cancer research, the British Empire Cancer Campaign has begun the publication of a new journal, the *Cancer Review*. It will consist wholly of abstracts and reviews of the current literature dealing with cancer. The management committee, which includes the directors of the Imperial Cancer Research Fund, the Cancer Hospital Research Institute, and the Lister Institute, as well as Mr. Sampson Handley, Mr. Lockhart-Mummery, Professor Lazarus-Barlow, and Dr. Major Greenwood, was under the chairmanship of Sir William Leishman until his death, and Dr. Francis Cavers, the general editor, is assisted by a committee of eight members representing different lines of cancer research. The first number of the new review contains 127 abstracts, which are grouped under the headings: general, experimental and biochemical, clinical and pathological, radiological, and statistical. It is thus rendered possible for each reader to recognize at a glance those abstracts which are likely to be of more particular interest to him. An alphabetical index of authors is provided also, so that the progress of research work in all lands, as shown by the publication of articles, can be watched. The *Cancer Review* will undoubtedly receive a warm welcome from all who are interested in the prevention and treatment of this disease, whether from the standpoint of therapeutics or pathology. It is hoped that through it the co-ordination of the work of cancer research centres throughout the world will be rendered closer, and the danger of overlooking or underestimating the results of individual researches will be substantially decreased. In the short introduction to this first number there is a request that all articles, books, and journals dealing directly or indirectly with the problems of cancer may be sent as they appear to the editor of the *Cancer Review*, at 19, Berkeley Street, London, W.1.

PROFESSOR THEMISTOCLES ZAMMIT was presented, on June 24th, with an illuminated address and his portrait in oils on the occasion of his retirement from the office of Rector of Malta University, which he has held since 1920. Dr. Zammit, who was born in 1864, graduated M.D. at Oxford, and for nearly forty years has been engaged in the service of the Government of Malta as public analyst. He was a member of the Mediterranean Fever Commission in 1904-7, and has held the chair of chemistry in the University of Malta since 1905. He has been curator of the Malta Museum since 1903, and his work in this connexion has received world-wide recognition. He was elected an honorary Fellow of the Royal Anthropological Institute of Great Britain and Ireland in 1919, and contributed in 1924, in collaboration with Dr. Charles Singer, to the *Journal* of the Institute an interesting paper on Neolithic representations of human form found in the islands of Malta and Gozo. He received the C.M.G. in 1911, and the University of Oxford conferred upon him the honorary degree of D.Litt. in 1920. In 1921 he was elected to the executive and legislative councils of the Malta Government. He was a member of the Malta Branch Council of the British Medical Association from 1917 to 1923, when he was elected president of the Branch.

# NINETY-FOURTH ANNUAL MEETING of the British Medical Association, NOTTINGHAM, 1926.

**T**HE ninety-fourth Annual Meeting of the British Medical Association will be held at Nottingham this month under the presidency of Mr. R. G. Hogarth, C.B.E., F.R.C.S., senior surgeon to the Nottingham General Hospital, who will deliver his address to the Association on the evening of Tuesday, July 20th. The Annual Representative Meeting, for the transaction of medico-political and administrative business, will open on the previous Friday, July 16th. The sectional meetings for scientific and clinical work will be held on Wednesday, Thursday, and Friday, July 21st, 22nd, and 23rd. The names of the officers of the thirteen Sections are published in the SUPPLEMENT this week, together with the provisional programme of arrangements for the Annual Meeting. On the last day of the meeting (Saturday, July 24th) there will be excursions to places of interest in the neighbourhood. The article printed below is the fifth of a series of descriptive and historical notes on Nottingham and the neighbouring country. The earlier articles appeared in the JOURNAL of December 5th, 1925 (p. 1081), January 23rd, 1926 (p. 158) March 20th (p. 541), and June 5th (p. 957).

## THE MEDICAL INSTITUTIONS OF NOTTINGHAM.

THE city cannot claim to have any hospitals with very ancient foundations, but is well provided with modern ones, both charitable and otherwise. History, however, does tell of one institution, the Hospital of St. John the Baptist, which was in existence in 1208, but is long since defunct. It is interesting to note that among its various duties was the "care and reparation of the Bridge of Nottingham." The earliest of the modern foundations is the General Hospital, which will stand comparison with most institutions of the kind. In addition there are the

in 1781 by His Grace the Duke of Newcastle and the Corporation of Nottingham. The cost was £5,861, and the hospital contained 44 beds. Ten more beds were added in 1784. In 1854 the hospital was added to considerably, the main building being raised a story and the chapel and day wards erected at a total cost of £4,872. In 1878 divisions 6 and 7, adjoining Park Row, containing 51 beds in all, were built.

In 1900 the Jubilee Wing was opened, having been erected by public subscription to commemorate the Diamond Jubilee of Queen Victoria. The wing, which is circular,

Architectural drawing of new building (Ropewalk Wing) for the Nottingham General Hospital.

various special hospitals mentioned below, the fine Poor Law hospital at Bagthorpe, and several others, and it is most satisfactory to note the increasing co-operation between the staffs of the various hospitals, which is so essential for the advancement of science and the treatment of disease.

### GENERAL HOSPITAL.

This hospital stands in a high position overlooking the park, in close proximity to the castle, and commands wide prospects towards the south. The site is historically famous, as it was here that Charles I raised his standard at the outbreak of the civil war. The hospital was established in 1782, two acres of land having been given for the site

contains three floors for patients, the ground floor being utilized as cubicles for a portion of the domestic staff, while the basement is used as store rooms, etc. There are in this wing 79 beds, 48 being for male surgical cases and 31 for children.

The further extension of the hospital was delayed on account of the great war, but in 1919 steps were taken to increase the accommodation. The first step was to erect a nurses' home. The cost of this was defrayed by a public subscription as a Nottingham and Notts War Memorial. The total cost was £75,000. There are at present 131 bedrooms, each nurse being provided with a separate room. As the hospital is a recognized training school for nurses, the home is suitably equipped with classrooms, where the

probationer nurses receive two months' preliminary training under a tutor sister before entering the wards. There are also recreation and sitting rooms for the sisters, staff nurses, and the nurses in training, and hard and grass tennis courts are provided. The home, which may be considered one of the most modern of its kind in the kingdom, was opened by H.R.H. the Prince of Wales on August 1st, 1923.

The new buildings now in course of erection at the corner of Park Row and the Ropewalk, known as "the Ropewalk Wing," consist of a new out-patient department, with large waiting hall, consulting rooms, etc., new x-ray, orthopaedic, electrotherapeutic, and massage departments, together with operating theatres and 40 beds for ear, nose, and throat cases. The total cost will be about £80,000. The buildings communicate with the hospital by a subway under Park Row. The heating, lighting, etc., will be supplied from the present hospital plant. Although it will be some months before the premises are in actual use, they are sufficiently advanced in construction to be fit for inspection.

#### NOTTINGHAM AND MIDLAND EYE INFIRMARY.

It was not until 1859 that, with the growth of the mining and textile industries, Nottingham decided to provide itself with a special institution dealing with affections of the eye, and the Eye Dispensary was opened in Parliament Street. In earlier times sufferers used to bathe their eyes with the waters of certain local springs and wells, hence the name "Rag Spring." This first institution was soon found to be too small, and within a few months a move was made to St. James's Street; here it assumed its present title, and secured the services of Dr. Bell Taylor as one of its first honorary surgeons, an association which remained unbroken till his death fifty years later.

In 1860 six beds for the treatment of in-patients were added, and good work was done in what would now be regarded as hopelessly insanitary surroundings, until, in 1912, a handsome new building was erected on the Ropewalk. Even this has recently had to be extended, and now includes a wing of paying beds for those unable to afford the usual nursing home charges, in addition to the forty ordinary beds. It is well equipped with modern appliances, such as the giant magnet, slit-lamp, etc. It draws on a population extending as far as Skegness in the east and Burton-on-Trent in the west, and deals with about 700 in-patients and 30,000 attendances yearly.

#### COLLIN'S TRUST MATERNITY HOSPITAL.

This hospital, in Waverley Street, takes its name from Abel Collin, a generous citizen of Nottingham, who lived in the reign of Queen Anne. The hospital was started by the trustees of his charity with funds which they allocated for the purpose, aided by a grant from the Ministry of Health, as, apart from the wards in the Poor Law hospital and nursing homes, there was no maternity hospital in Nottingham. The project was under consideration before the war, but it was not until near its end, when the need of safeguarding the pregnant mother and her child became more urgent, owing to housing and other difficulties, that a small beginning was made by the purchase and equipment of a house in Waverley Street to admit 12 mothers and 12 babies. There, since June, 1919 (the first case to be admitted was for contracted pelvis and had Caesarean section performed), with many difficulties owing to limited accommodation, the work has been carried on, including ante- and post-natal clinics and training of midwives, the hospital having been

recognized as a training school by the Central Midwives Board since 1920. After many delays a new hospital at "The Firs," Sherwood, for 32 mothers and 32 babies, has been nearly completed, and when funds permit it will be possible to extend the accommodation so as to admit 60 mothers and 60 babies, as was planned in the original scheme.

#### NOTTINGHAM HOSPITAL FOR WOMEN.

This hospital was opened in a private house in Castle-gate nearly fifty-one years ago. The real founder was Miss Catherine Woods, a great-aunt of the present Bishop of Winchester. She had been brought up in Quaker traditions of usefulness to her kind; and it was while visiting in the wards of the General Hospital that some of the women patients gave her the suggestion of a small, homely hospital for women only. Perhaps then—we do not know—as in other hospitals of the time, the babies and children were nursed in the women's wards. At all events there arose between those unknown women and Miss Woods the idea of a hospital on lines which have now become those of the most modern of these institutions. There were to be no recommendations, and therefore no temptation to admit a patient for any reason other than her need and fitness for treatment. Those who wished to befriend a patient could pay her modest fees for a part or the whole of her stay.

To complete the anticipation of modernity, some years later a private department was begun. These patients under the care of the hospital staff paid a sum

covering the full cost to the hospital, which made no profit out of them. The nursing home had not yet been born in Nottingham, and these private beds have been an unspeakable boon.

Meanwhile the Samaritan Hospital for Women was started in Raleigh Street in 1885, and has for thirty-nine years done a great amount of splendid surgical work. In 1924 the two hospitals contracted a happy marriage, and their life under one roof waits only for the building of the new hospital.

Last year 537 in-patients were treated in the combined hospitals, with 531 operations. Out-patients numbered 8,528, of whom 2,112 were new.

For many years a building fund had slowly been accumulated, and some years ago an admirable site with a good house in Peel Street was purchased. The site is central, yet, overlooking the Arboretum, sure of quietude and fresh air. It is let to a nursing home until the hospital is ready to build. The committee now waits only for a little better times to complete the plans and to appeal to the public to help those who have worked hard to help themselves.

#### NOTTINGHAM CHILDREN'S HOSPITAL.

The institution of a children's hospital must be placed to the credit of a noble band of philanthropic workers who were intimately associated with the management of the Nottingham General Hospital, and who, about 1869, came to the conclusion that the provision for free medical treatment of children suffering from various ailments and diseases was altogether insufficient. Probably the Rev. and Hon. C. J. Willoughby, rector of Wollaton, should be placed first, then the Rev. Henry Seymour, rector of Holme Pierrepont, and associated with them was the Rev. James Matheson, minister of Friar Lane Chapel, Mr. Abraham Cam, solicitor, acting as honorary secretary, Mr. T. C. Hine being the architect.

After deliberation they decided to purchase the house of the late Alderman Knight in Postern Street and Amberley Street, which was altered and adapted. Sister Mary

Children's Hospital, Nottingham.

Mellicent was the foundress and first sister-in-charge, the hospital being opened in July, 1869. When more room was needed Mrs. Violet Jacoby, mother of Sir Alfred Jacoby, M.P., in 1878 spent about £800 in making the necessary additions. When the removal to Forest House, as mentioned hereafter, took place, the property above described was sold to Sir Charles Seely, Bt.; presented to the General Hospital, and connected therewith by a bridge crossing Postern Street.

Sir Thomas Birkin, Bt., having purchased the estate of the late Edwin Patchett in 1899, presented to the committee of the Children's Hospital the house and grounds known as Forest House, which is situated in the healthiest part of the city, stands high, is open on every side, and is very conveniently situated. This valuable gift required a considerable sum to be spent in alteration and adaptation.

In the year 1870 the total income of the hospital was £391, the in-patients for the year numbering 37, the out-patient attendances being 98. To-day the expenditure is approximately £7,600 per annum, the in-patients numbering 600 and the out-patient attendances being approximately 120 a day.

The hospital is equipped with separate modern operating theatres for in-patients and out-patients, with up-to-date x-ray plant, ultra-violet ray lamps, and massage and electrical departments.

As the present premises are inadequate and somewhat out of date, a new hospital is being erected by the generosity of Mr. and Mrs. J. D. Payer. Unfortunately the building is not completed, but it will be sufficiently far advanced for inspection by those attending the Annual Meeting of the British Medical Association in July. When completed the building will accommodate about eighty in-patients, and will be equipped on the most modern and up-to-date lines. The design is the work of Mr. J. Rigby Poyser, L.R.I.B.A., architect, of Nottingham, in consultation with Dr. D. J. Mackintosh, C.B., of Glasgow. The out-patient department is to be considerably increased and the old house modernized; this will make an admirable residence for nurses and staff.

#### NOTTINGHAM AND NOTTINGHAMSHIRE HOSPITAL FOR DISEASES OF THE THROAT, EAR, AND NOSE.

This hospital, in Shakespeare Street, was founded in 1888 by the late Dr. Donald Stewart. It has a very large out-patient department, between 2,000 and 3,000 new patients being seen every year. There are 14 beds, which are kept continually occupied; nearly 400 operations are performed there annually. The board of this hospital was one of the first to realize that tonsil and adenoid operations should be kept in hospital for at least thirty-six hours after the operation is done. Patients pay a small sum towards the upkeep of the hospital, which is also supported by voluntary contributions from private friends, workmen's clubs, etc.

#### NOTTINGHAM UNIVERSITY COLLEGE.

The foundation stone of the University College was laid on September 27th, 1877, by the Mayor, Alderman J. W. Bowers. The College was opened on June 30th, 1881, by H.R.H. the Duke of Albany, and the first session began on October 1st of that year. All provision for the higher education of adults was gathered into the College, and facilities for day and evening studies were afforded to all without distinction. The College was affiliated to the Universities of Oxford and Cambridge in 1883. From its foundation until 1903 it was governed by a committee of the town council. On August 27th of that year a Royal Charter of incorporation was granted, vesting the College in a court of governors consisting of the City Council, with a president and vice-president elected by them.

The present technical schools were opened on January 12th, 1893, by the Master and Wardens of the Drapers' Company of the City of London.

New university buildings are now being erected in University Park, at a cost of £250,000. This has been made possible by the great generosity of Sir Jesse Boot, Bt., who has not only provided the site and very large sums towards

the cost of the buildings, but has given to the city and laid out at a cost of hundreds of thousands of pounds the park itself, which provides a beautiful setting for the new buildings.

The College prepares for degrees of the University of London; and for diplomas in commerce, social study, geography, chemistry, pharmacy, physics, education (elementary and secondary), engineering, mining and mine surveying, hosiery manufacture, and dyeing and finishing. It is divided into four faculties: the Faculty of Arts, including departments of English, history, classics and philosophy, modern languages, education, extramural education, and music; the Faculty of Economics and Commerce, including the departments of law and social study; the Faculty of Pure Science, including the departments of chemistry, metrology and physics, mathematics, biology and bacteriology, geology and geography; and the Faculty of Applied Science, including the departments of engineering, technology, mining, and textiles.

There are four halls of residence connected with the College: Mapperley Hall and Waverley House for men, Cavendish House and Hollygirt for women. During the session 1925-26 there were 722 day students and 2,036 evening students in attendance. The social side of the College is in the hands of the students' "Union," which has the control of all clubs and societies. The tennis ground, with ten courts, is situated in Elm Avenue, and the athletic ground in University Park, where provision is made for cricket, hockey, netball, tennis, and football (Rugby and Association).

The Scientific Sections of the Annual Meeting of the British Medical Association will meet in the theatres, classrooms, and laboratories of University College.

#### LONDON HOSPITAL MEDICAL COLLEGE.

##### PRIZE DISTRIBUTION.

The distribution of prizes to students of the London Hospital Medical College and Dental School took place, as briefly announced in our last issue, on June 28th. The Chairman of the College Board, Lieut.-Colonel W. Manborough Pryor, presided, and the proceedings began with the reading by the DEAN (Professor William Wright) of his report on the work of the college during the past year. In noting some of the principal honours and distinctions won by past and present students and members of the staff, the Dean mentioned that a very distinguished son of the London Hospital, Sir Neville Howse, V.C., a former Minister of Education and Health in the Australian Government, had just been appointed by that Government to be its High Commissioner in London. A year ago he had been able to announce that during 1924-25 the college had received three donations each of £10,000, to be applied respectively to the promotion of medical research, the building of a new clinical theatre, and the reconstruction of the Pathological Institute. The present year had been signalized by a munificent gift from an anonymous donor of £50,000, which had been applied to the endowment of a "Freedom Research Fund," the whole of the income being devoted to medical research. With the new hostel for resident medical officers, and the prospective building of a new cardiological department, the year 1926 would take its place architecturally also as one of the most important and eventful in the history of the London Hospital.

##### Address by the Minister of Health.

The Right Hon. NEVILLE CHAMBERLAIN, Minister of Health, after distributing the prizes to successful students, gave an address on the organization of medical services. After touching on the great variety of choice and great diversity in the possible careers of those who had studied at the hospital, he thought there would nevertheless be amongst them all many common thoughts, common ideals, and common associations which would, in spite of everything, preserve in them a spirit of comradeship. Above all, there would be that attitude of mind which, as he sometimes thought, distinguished members of the medical profession from ordinary people and made them, to a

certain extent, a people apart. No one who had been in intimate contact with any practising surgeon or physician could doubt his fundamental seriousness of outlook. He did not mean that doctors had no sense of humour: God forbid! their worst enemies had not accused them of that; but inevitably there must be in them a serious vein. They must feel that their calling was something beyond a mere means of earning one's livelihood, that they had a purpose in life which was neither selfish nor superficial; and as far as he had been able to observe it, without an exception practically, they conscientiously strove to achieve that purpose. And so he could not help feeling that, in speaking to medical students, he was addressing men who would be inclined to listen sympathetically to any consideration of the problem which lay before a Minister of Health: a problem not concerned with the cure of the individual, but rather with the much wider task of trying to improve the general health of the people. There were a good many factors at work in the solution of that problem, and every student, no matter what branch of the profession he took up, could give a helping hand to the Minister, and make his contribution towards the solution of this problem. Take, for instance, the prevention of disease; in many cases the conditions of life—not in the big towns alone, but in the smaller villages, and even right in the country—were simply manufactories of disease; and while certainly everything possible must be done to combat the results, it would be at once cheaper and more effective if the source of the trouble could be destroyed. Then, again, how important it was to ensure the early detection of disease and the right treatment of its first beginnings. The doctor who had completed his studies at college or medical school should not think that thereby he had finished his education; it was only too easy, in the remoteness perhaps of a country practice, to get behind the times, to get out of date, to acquiesce in a certain lethargy, when there was but little competition and hardly any criticism. Again, medical knowledge nowadays had got so wide and so complicated that it was more than any one man could possibly assimilate, so that treatment, to be complete, should be a matter of team work. And, still from the point of view of the Minister of Health, hardly too much stress could be laid upon the continual prosecution of research. But research was not one of those things which lent itself to mass production.

In conclusion, Mr. Chamberlain said that his object in making these remarks was to bring to the minds of those who were beginning their careers the idea that they had something more before them than the treatment of individual cases; that, in fact, whatever branch of the profession they might adopt, they were all parts of a great army whose objective lay beyond the section of the enemy immediately in their face. The process which he, as Minister of Health, at the present moment was trying to advance was an endeavour to make better use of the forces at their disposal. The organization of medical services in this country was far from perfect. The heavy artillery, in the shape of institutions, was not only inadequate in quantity, but often badly sighted. The intelligence was understaffed, and the results were not always available to the fighting units. There was insufficient co-operation between commanders, and the rank and file were not always in complete touch with their officers. It was the task of the Minister of Health to try to remedy these defects; to correct anomalies; to adjust the machinery, so that it might be better adapted to changing conditions. That was a difficult and sometimes painful process, and so the Ministry was subject to frequent criticism. He hoped that his hearers, as they went through life, would take a broader view; that they would sympathize with the Minister, whether it be himself or his successor, who was struggling against inertia and against prejudice, against want of faith and want of money, and that they would try in their respective spheres to lend him a helping hand. With that idea in the back of their minds they would find their own life more interesting and their own work more satisfactory, because they were not only doing the work which immediately lay before them but contributing also in their own way to the general benefit.

#### *Lord Knutsford on the Hospital's Ideal.*

LORD KNUTSFORD, in proposing a warm vote of thanks to Mr. Neville Chamberlain, said that those to whom he had given the prizes were recruits in the work which he had made his own. As chairman of the hospital he entirely sympathized—they all did—with what Mr. Chamberlain had said: that their duty did not end with simply curing the sick people in their wards who came to them for help; they had to try to find out the causes of sickness, and their work in this direction had only been limited by their means. The ideal of the hospital was not to increase its beds, but to make that terribly long waiting list impossible—to make the beds unnecessary because they had tackled disease at an earlier period and the vast community they served would not need the hospital as much as it did to-day. Until 1924 they despaired of being able to do any preventive work at all. That great hospital, the largest in the country, had only £25,000 for the endowment of medical research. But since then a change had come. The Dunn trustees had given beautiful laboratories: Mr. Williams had helped to endow them. Lord Bearsted had given a clinical theatre with a lectureship attached; and Mr. Bernhard Baron gave the pathological institute, which would soon be built. Lastly they had the magnificent donation from the "Freedom Research" donor, to which the Dean had referred.

#### *Lord Dawson on Medical Practice of the Future.*

LORD DAWSON OF PENN, physician to the hospital and chairman of the Medical Council of the College, in seconding the vote of thanks, said that the Minister had pointed out in the course of his interesting speech the changes that were coming over medicine, or rather, in the practice of medicine. And it was true, both as regards hospitals and as regards practitioners, that those changes were likely to be wide and deep. The hospital, or rather teaching hospitals, whatever changes might befall them, as long as they clung to the ideals by which they had become great, were likely to live, to stand for the welfare of the country in the same sense as they had done in the past. They would remain, as now, national institutions. It was interesting to reflect that certain changes would take place in the methods of practitioners' work. The centre of gravity was drifting away from disease and towards health. The doctor of the future would study early disturbances of function. His time would be concerned more with the threshold of disease. And, further than that, in addition to his work with individual patients, he would probably be thrown in contact with groups of people resembling each other, either in their attributes or their occupations. Apart from clinics, which were multiplying the land over—for example, those that concerned school children or maternity or tuberculosis—it seemed to Lord Dawson inevitable that there would be a large development in industrial medicine. It was inconceivable that the employers of labour could do anything but increase medical services in connexion with their large businesses, not only to the advantage of their employees, but to the economic advantage of themselves. That opened up a field of great interest. The doctor would have to concern himself with the lives of the people he had to look after; he would study them in relation to their work and in the environment of their employment, and an indirect result would be a diminution of practice in the surgery and the home. In short, the doctor would gradually move towards the study of the beginnings of disease and curative medicine. Apart from gratitude to the Minister for coming there that day to give them his encouragement, they valued his presence as an emblem of the unity of medicine. Another way in which medicine must alter was by an increase of clinics and hospitals; institutional provision for the sick would increasingly supplement the care of the sick in their homes. In that connexion, it seemed important for each to think out the functions that he would perform in these institutions. Primary hospitals of the future would play an important part in every local community, and doctors who practised in that community should have access to them. It might be asked, Did not all this mean changes in the curriculum? Changes in the curriculum were bound

to occur from time to time. The medicine of to-day was very different from that of fifty years ago. But although there would be a reframing of the curriculum, there would be no extension of its length. In conclusion, Lord Dawson said that there never was a time when medicine presented a wider outlook of interest and usefulness. Those on the threshold of their careers would long remember that occasion and recall the gratitude felt by them all to Mr. Chamberlain for his presence and the vision and inspiration of his speech.

In acknowledging the vote of thanks, Mr. CHAMBERLAIN said that Lord Dawson always brought to the consideration of any question, not only his great professional ability and experience, but also a width of view and a statesmanship which made him simply invaluable to the Ministry of Health. As for Lord Knutsford, the popular idea was that he owned the London Hospital! It was certainly true that he had provided most of the capital for it. When he had got his £100,000 an unremunerative but useful position would be open to him as liaison officer between the Ministry of Health and the Chancellor of the Exchequer. (Laughter and cheers.)

## Union of South Africa.

[FROM OUR CORRESPONDENT IN CAPE TOWN.]

### THE 1926 CENSUS.

THE preliminary results of the census recently completed have been published. Since 1921 the white population of the city of Capetown has increased from 55,000 to 60,000, while the non-European increase is from 51,000 to nearly 59,000. The inhabitants of Greater Capetown, which comprises Capetown proper and suburbs, excluding the separate municipalities of Wynberg and Simonstown and certain smaller areas which have their own local governing boards, now number 268,709, compared with 185,765 in 1921. That the non-European element has increased more rapidly than the European is proved by the fact that the rise in the white population amounts to 9,000, as compared with 14,000 in the case of the coloured community. The preliminary figures for Kimberley show that since 1921 the white population has decreased by 1,409, the respective totals being 21,607 and 20,198. At Stellenbosch, on the other hand, a remarkable increase in the European population of the district has occurred, from 11,411 in 1921 to 13,188 (males 6,596, females 6,592). The town of Stellenbosch numbers 4,422 Europeans as against 3,701 five years ago.

### HOSPITAL NEEDS OF CAPE TOWN.

At a meeting of the Cape Hospital Board on May 26th a memorandum by the chairman, Mr. M. C. Vos, was submitted dealing with certain points raised in a resolution recently passed by the board calling for investigation into means of extending hospital accommodation and treatment while awaiting completion of the proposed new general hospital at Groot Schuur. The matters dealt with in the memorandum may be classified as follows: Out-patient departments and free dispensaries; district nursing service; extension of existing hospital accommodation; convalescent homes; and new maternity home.

The memorandum points out that there are in existence out-patient departments at the New Somerset Hospital and at the Woodstock Hospital, as well as the Capetown Free Dispensary. To all intents and purposes only the urban area proper and the immediately adjoining suburbs of Woodstock, Salt River, and Observatory are thus catered for. It is proposed, therefore, to establish a new dispensary at Wynberg, and, if possible, another at Claremont. Even more urgent is the claim of a very large area comprising the suburb of Maitland and its neighbourhood, where there is a large poor community. To meet the expense involved it is suggested that the Provincial Administrator be requested to sanction a loan, failing which certain moneys belonging to the Capetown Free Dispensary for capital expenditure exclusively—about £5,700—be drawn upon, provided some agreement can be arrived at with the committee of the Free Dispensary. The District

Nursing Service consists of eight district nurses working under the charge of a superintendent of district nurses. The necessity of devising some means for making the service as effective as possible is another subject to be considered, but whether by increase in the number of nurses or by redistribution of areas supplied is not stated. The new General Hospital, which in the first instance is to contain 300 beds, to be increased later to 500, will not be completed for at least five years, at the expiration of which period it may prove to be inadequate to supply the needs of the by then greater population. The solution of this problem would appear to be the immediate increase in the number of beds at the existing hospitals under the control of the board. The ward in which the male V.D. patients are housed at the New Somerset Hospital is in a sad state of dilapidation, and should be closed, cleansed, and renovated. To provide for the efficient treatment of such patients negotiations are already in progress with the medical officer of health for the city with a view to the necessary accommodation being provided at the City Hospital, where, too, clinical teaching to students will be carried on. A proposal to provide a new casualty ward at this hospital, at an estimated cost of £1,200, is under consideration. More extended additions to it are not contemplated, however, as the buildings are eventually to be demolished. At the Woodstock Hospital, by utilizing the nurses' quarters at present situated in the hospital building itself, and providing additional accommodation in the nurses' home, an addition of twelve beds may be reckoned on. At the Rondebosch Hospital two new wards for non-European patients have already been erected. When these are occupied the quarters vacated could be made to furnish twelve additional beds. The suggestion has been made to build at the Wynberg Hospital an entirely new block for coloured patients with accommodation for thirty beds, and adjoining it a new ward with ten beds for coloured children. Part of the existing building might then be utilized as quarters for the house-surgeon, an office recently created, and also for a dispensary. The net increase in beds under this scheme would be twenty-two, entailing an expenditure of about £5,000. The Simonstown Hospital is adjudged large enough for its present requirements, serving as it does an outlying district with a limited population. With regard to convalescent homes, it is recommended that beds should be added to those at present existing, and that an adequate staff of trained nurses should be provided so that cases requiring further treatment may be transferred from the hospitals to make room for more urgent cases. The average stay of patients at the New Somerset Hospital should in this way be reduced from thirty-two to eighteen or twenty days. The erection of a new building at the Eaton Convalescent Home to accommodate from thirty to forty cases is contemplated. Lastly, while in no way intended to compete with the new maternity block at the hospital to be erected on the Groot Schuur site, the provision of a new maternity home in District 6, the slum quarter of the city, is an urgent need, and should be used for the training of midwives.

Speaking generally, the proposals suggested to relieve the present congested state of the hospitals and provide additional accommodation, etc., will involve an expenditure of approximately £20,000, and in this way the period of five years until the new hospital is built would be tided over. At the same time it must be borne in mind that these additions will be of a permanent nature and will be required to meet the demands of a growing population. As the New Somerset Hospital has been sold for £100,000, and as it would be possible to raise this money immediately from the Provincial Administrator, the chairman, with reference to his memorandum, suggested that a portion of this sum should be utilized to enable the board to proceed with the improvements outlined.

### APPOINTMENTS.

Dr. Robert Sharp, honorary medical superintendent of the Woodstock Hospital, has been appointed acting medical superintendent of the New Somerset Hospital, in a part-time capacity, at the salary of £1,000 per annum. Dr. Sharp is to devote four hours a day to the duties of the

office. Owing to the fact that, for the time being, he is a paid official of the Cape Hospital Board, Dr. Sharp has had to relinquish his seat on the board, his membership of the committee of the Woodstock Hospital, and also his appointment as honorary medical superintendent of the last-named institution. Dr. Z. J. de Beer has been appointed district surgeon for the area of Woodstock in succession to Dr. Robert Sharp. Major F. W. Cluver, South African Medical Corps, has assumed command of the Wynberg Military Hospital, vice Major van der Spuy, who has been promoted to command of the military hospital at Roberts's Heights, Pretoria.

#### GOLF.

The competition for the Jones-Phillipson cup, held under the auspices of the Cape of Good Hope (Western) Branch of the British Medical Association, and open to all medical men resident in the area, was decided on the course of the Royal Cape Golf Club on May 19th. The winner proved to be Dr. W. P. Mulligan, who returned a net score of 77. The competition was first held in 1923, when a floating trophy was presented by Mr. C. E. Jones-Phillipson, then president of the Branch. The first holder was Dr. G. B. Wilkinson of Seapoint; in 1924, and again the following year, Mr. E. Barnard Fuller, a past president of the Branch, carried off the honour.

## England and Wales.

#### A SUSSEX ORTHOPAEDIC CENTRE.

ON the day following the inauguration of the Welsh Branch of the Central Committee for the Care of Cripples (see p. 79) a party of about fifty medical officers of health and other representatives of local authorities in Wales paid a visit to Chailey in Sussex to inspect the Heritage Craft Schools and Homes for Crippled Children. Sir Robert Jones, who is chairman of the medical board at Chailey, and Sir John Lynn-Thomas, the honorary secretary of the newly formed Welsh organization, acted as hosts. The visitors were received by Mrs. C. W. Kimmins, who founded this work more than twenty years ago and is now its honorary secretary, and by Dr. Murray Levick, the medical director. The schools, which contain 150 boys and 70 girls, rose to the occasion, the Welsh dragon fluttered at every point of vantage, and the cripples—a brave deed, since they were English—delighted their guests by singing Welsh songs. There was much to see, and hardly time to appreciate the glorious scenery, between the east and west downs, in which Chailey is set. The hospital block, provided by Sir Jesse and Lady Boot, with the wards, open-air balconies, and light-treatment rooms planned in a single unit, was first visited. The combined method of treatment which is given was demonstrated by the staff. Dr. Murray Levick mentioned also some good results which had been obtained in infantile paralysis, even in muscles which gave no response to the interrupted galvanic current. The treatment consisted of general irradiation by "artificial sunlight" (or by real sunlight when this was available), local treatment of the affected muscles by rays from long-ray lamps passed through red filters, electrical treatment, re-education of the voluntary stimulus, and instrumental support for the paralysed muscles which, often at an early stage, can be abandoned, and, finally, massage. Out of doors, stretched on canvas couches, the children were seen receiving their sun treatment, combined with school lessons, the prone and supine positions being alternated at regular intervals under the direction of a nurse while the lessons proceeded; in the gymnasium some boys suffering from advanced kyphosis were taken through physical drill and deep-breathing exercises. The visitors were also bidden to admire the craft work produced in the Lord Llangattock workshops, where the cripples are taught the subjects of the elementary school curriculum as far as possible through the medium of their craft, working in wood as other children work in copybooks. After a visit to the beautiful little church, where a tablet records the names of a considerable number of ex-patients from Chailey who served in the war,

the party went to the girls' school on the other side of the common, where, on the lawn, Miss Margaret Morris illustrated her system of exercises which has been selected as most suitable for the crippled girls. Here also children of quite tender years, as young as 2, were shown receiving sun baths. The party then journeyed to Lowes for luncheon, at which messages welcoming the Welsh visitors were read from the patron, H.R.H. Princess Louise, the Bishop of London, the president, and Sir George Newman, K.C.B., M.D. Two Labour members of Parliament for South Wales, Colonel Watts Morgan and Mr. William Jenkins, expressed the thanks of the visitors to Sir Robert Jones and Sir John Lynn-Thomas for an interesting day, and said that they and others would not rest until they had in the principality some equivalent to Chailey. Sir Robert Jones said, in response, that Chailey might be called the public school of crippleddom in this country, and everyone who came within its influence went out to preach its gospel. Sir John Lynn-Thomas, who also spoke, mentioned that it was while he was stationed in the South of England during the war that some part of this work—that at Tidemills, which was to be visited later—came under his observation, and stirred an enthusiasm within him which had never died down. In the afternoon, before returning to London, the visitors proceeded to the marine annexe at Tidemills, and saw how the principles of combined school and cure were being applied.

#### MEDICAL WOMEN'S FEDERATION.

The annual general meeting of the Medical Women's Federation was held on June 17th, under the chairmanship of Miss Frances Ivens, the retiring president. It was agreed that £100 should be given to the Dame Louisa Aldrich-Blake memorial fund as a contribution to the proposed scholarship fund. The federation was asked to invite contributions from its members, the whole sum collected to be handed over to the memorial in the name of the federation. Dr. Christine M. Murrell was elected president, Dr. Ellen B. Orr and Dr. Clara Stewart vice-presidents, and Dr. Jane Walker honorary treasurer in place of the late Dame Louisa Aldrich-Blake, who had held that office since the foundation of the federation. These, together with Miss Frances Ivens, Lady Berry, honorary secretary, and Miss Mabel Ramsay, elected from the council, compose the executive committee for the coming year. Dr. Frances Braid of Birmingham reported that a bed at the Taylor Memorial Home for Incurable Diseases had been dedicated to the memory of Dr. Mary Sturges as a memorial from the federation. The aviation subcommittee reported that the various qualities which produced the "flying aptitude" were found in women as in men. It had specially considered the question of menstruation and pregnancy in relation to women's fitness for flying and for receiving aviation certificates. In this connexion it had examined the results of recent research into the effect of menstruation on the various processes of the body, especially the work at the London School of Medicine for Women, under the direction of Professor Winifred Cullis, which showed that there was no change during menstruation in basal metabolism, pulse rate, or blood pressure, and also that the cost to the organism of a certain amount of work and the recovery rate from work was the same both during menstruation and the intermenstrual time. The subcommittee had concluded that normal menstruation was no bar to flying, and considered that the searching and repeated medical examinations already in force in regard to those holding certificates would be sufficient to prevent unfit persons from undertaking flights.

The national corresponding secretary of the Medical Women's International Association reported that the medical women of Canada, and still more recently those of Mexico, had formed associations which had joined the International Association. She reported the rapid growth of the German Medical Women's Association, which now numbered 650 members, issued a quarterly journal, and published a list of members with the type of practice undertaken by each. A meeting of the council of the International Association would begin on August 26th in Prague. At the request of the British Medical Association Miss Mabel Ramsay and Miss Louisa Martindale

were appointed to serve on the Special Committee to consider the report of the Royal Commission on the Insurance Acts. A new standing committee on public health was formed to watch public health developments, including posts advertised. An invitation to hold the next meeting of the council at Leeds was accepted. On June 17th Miss Ivens gave a dinner at the Welbeck Palace Hotel, and on the 18th a lunch was given at the London School of Medicine for Women by the dean, Lady Barrett, at which many of the women members of the school and hospital staff were also present. On the evening of the 18th a *conversazione* was held by the London Association of the federation in the Hastings Hall of the British Medical Association House. Sir James Berry gave a lecture on Greek temples in Sicily, and Lady Berry described scenes and episodes of travel in various climes, under the heading "Scattered recollections." Both lectures were illustrated by lantern slides from photographs taken by Lady Berry.

#### BIRMINGHAM MENTAL HOSPITALS.

The Asylums Committee at Birmingham is reviewing the administration of the institutions under its control, and has recently submitted a scheme for greater unification to the Board of Control. It is proposed to make Dr. T. C. Graves, medical superintendent of the Rubery Hill and Hollymoor Mental Hospital, chief medical officer of the various institutions, though he will continue to reside at Rubery. Dr. Forsyth, assistant superintendent at Rubery, becomes medical superintendent at Winson Green, a position now vacant by the retirement of Dr. Cecil Roscrow after twenty-three years' service. Dr. Elizabeth Selkirk, for many years on the staff at Winson Green, has been appointed medical officer in charge of Hollymoor, and so becomes the only lady superintendent of any large mental hospital in this country. The three mental hospitals have about 2,250 patients under their care.

#### STERILIZATION OF MENTAL DEFECTIVES.

The Mental Hospitals Committee of the London County Council has considered a resolution which has been adopted by the Worcestershire County Council urging the Government, in view of the increase in the number of mental defectives, and the heavy cost of maintaining and extending institutional treatment, "the effect of which is usually most unsatisfactory," to take such compulsory measures as it might deem best for preventing the spread of this condition by sterilization, by compulsory segregation, or by other measures. The London Mental Hospitals Committee states that it has more than once considered whether sterilization by surgical operation might be resorted to as a prophylactic against mental deficiency, but it had concluded that there were too many practical difficulties to permit of the endorsement of any proposal to make such a measure possible. That was still its opinion. So far as compulsory segregation was concerned, this was available at present in certified institutions for cases that could be dealt with under the Mental Deficiency Act. The committee is not aware of any serious justification for the opinion that the effect of institutional treatment is usually most unsatisfactory, and adds that it is difficult to see what other measures are ever likely to be enforceable.

#### LEEDS SCHOOL OF DENTISTRY.

Twenty-one years ago the members of the Leeds and District Section of the British Dental Association decided to start a dental hospital for the treatment of patients who could not afford to pay fees and for the training of dental students. The hospital was equipped through the generosity of these dental surgeons and their friends, and was carried on for some years in the public dispensary, but as its work grew it became necessary to find new premises. This was made possible by two other public bodies—the authorities of the General Infirmary, who made room for part of the work, and the board of guardians, who provided accommodation in the East Leeds Infirmary for the rest of it. A few years later this latter portion of the work was transferred also to the General Infirmary, in which the whole of the activities of the dental hospital and

school have since been carried on. With the expansion of the hospital the training of dental students has also increased, and the institution now forms a combined dental hospital and school of great value to the county. There are now fifty-three students undergoing training in the school, and during last year 9,210 patients received treatment, entailing 28,350 visits. At an early stage the dental committee in charge of the hospital came to an arrangement with the university by which students could read for a degree or a diploma in dental surgery by combining courses in the university with their practical work in the hospital. In 1914 this arrangement was developed into a scheme of amalgamation by which the dental school became a department of the university within the Faculty of Medicine. The university now takes full responsibility for the whole of the educational work of the school, while the hospital work forms a department of the General Infirmary. For some time it has been clear that new premises would again have to be provided. The provision of a building for this department had therefore to be included among the urgent needs in respect of which the university issued its appeal for £500,000. A site, valued at about £8,000, has been provided by the General Infirmary authorities, the Dental Board of the United Kingdom has promised a grant of £5,000 contingent on the balance of the cost of the building being obtained from other sources, the honorary staff of the dental school have subscribed £2,000, and contributions have been received from other dental surgeons. The building, which will provide accommodation for 150 students and pupils, is to occupy a site on the north side of Blundell Street, adjacent to the medical school and the General Infirmary, and conveniently situated for the university.

## Scotland.

#### VICTORIA INFIRMARY, GLASGOW.

THE thirty-eighth report of the governors of the Victoria Infirmary, entitled as hitherto "annual," covers on this occasion a period of fourteen months, terminating December 31st, 1925, the financial year previously ending October 31st having been altered to coincide with the calendar year.

The total number of cases admitted during the period was 5,001; the mortality, excluding deaths within forty-eight hours, was 5.8 per cent. There were in addition 4,494 minor surgical cases, including accidents, and 2,268 patients were treated for diseases of the throat and nose. The average daily number of patients was 288, and the average length of stay in hospital 23.8 days. Contributions received from patients in recognition of services rendered amounted to £268. Employees' contributions for the year to December 31st totalled £11,006. The Bellahouston Dispensary, in a populous district of the south side of Glasgow near the docks, treated 37,661 patients for diseases of the eye, ear, nose and throat, and skin, as well as for medical, surgical, and gynaecological ailments. This dispensary, which does so much for a crowded neighbourhood, should receive more financial aid from local sources. Progress is being made with the new wing of the infirmary, which, when opened, will involve an additional annual expenditure of £14,000. The governors have purchased a piece of ground at Thorntonhall, in the country near Glasgow, for an auxiliary hospital. These extensions are amply justified by an average waiting list of 450. The Victoria Infirmary continues to render notable service to the community and merits every support.

#### GLASGOW EAR, NOSE AND THROAT HOSPITAL.

The annual general meeting of the Glasgow Ear, Nose and Throat Hospital was held on June 9th. Dr. Robert T. Moore, Lord Dean of Guild, who presided, said that Glasgow had one of the best equipped institutions of this kind in the United Kingdom, but an annual income of £7,000 was required to carry on the work. One of the directors, who desired to remain anonymous, had given an adjoining building to the institution. Dr. R. M.

Buchanan, President of the Glasgow Royal Faculty of Physicians and Surgeons, in moving the adoption of the report, said that the activity of this hospital was specially necessary in the atmosphere of Glasgow for the prevention of the serious disability which resulted from loss of hearing. He congratulated the directors and subscribers on the splendid new hospital they had provided, which made such a notable and valuable addition to the hospitals of the country.

#### ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

During the year ending December, 1925, the "record" number of 6,452 patients received treatment in the wards of the Royal Hospital for Sick Children, Glasgow, and an appeal by the directors for £75,000 to provide urgently necessary additions and extensions to the hospital was fully successful in less than six months. Completion of the extensions to the nurses' home, administrative offices, maids' quarters, and kitchen will enable further work to be begun, including the provision of departments for outpatients, orthopaedic work, and treatment by x rays and heliotherapy. The forty-third annual report of the hospital contains also the information that, in consequence of a generous gift, it will now be possible to extend the country branch of the hospital at Drumchapel. When this has been done the hospital and country branch will contain more than 400 cots, and will be one of the finest institutions of the kind for children in existence. Other gifts during the year include an electro-cardiograph, the equipment of a small dental department, various mercury and vapour are lamps to form the nucleus of a heliotherapy department, a microphotographic apparatus for use in the laboratory, and a small x-ray apparatus in the operating theatre block. An appeal is made in the report for the endowment of a university lectureship and a research department in connexion with the pathology of the diseases of infancy and childhood, which would enable full advantage to be taken of the special resources of the hospital. Although the general income considerably increased during the year, there was a serious falling off in legacies, and the expenditure of the hospital exceeded the income by nearly £4,000. The contributions of employees in public works and warehouses showed an increase over the previous year of £360.

### Correspondence.

#### REPORT ON RHEUMATIC HEART DISEASE IN CHILDREN.

SIR,—I am very unwilling to appear ungracious by offering any criticism of the report of a committee which voluntarily has undertaken the laborious and tiresome task of a statistical survey for the benefit of their less energetic colleagues; I venture to do so solely in the hope that while the data before the committee are still more or less in hand, one more piece of work may furnish something like a definite set of conclusions to their labours.

Those who daily are concerned with the question of tonsillar sepsis are, of necessity, alive to the fact that this is merely one element of tonsillectomy which do not include at least the dental factor must be misleading. In the case of the rheumatic subject who is most closely under my constant observation, a person devoid of tonsils, on three separate occasions, at long intervals, attacks of acute pain, swelling, and redness of the wrist have at once subsided, without other treatment, on the extraction of teeth from infected sockets. Such an experience is not exceptional.

Dr. Reginald Miller would be doing a great service if now, while he is in touch with his tonsillectomy cases, he would scrutinize their dental condition and history. In addition to the major problem, he possibly will find in the teeth an explanation of the interesting class incidence of rheumatism to which he alludes in his important contribution to the report on environmental and other predisposing causes of rheumatic infection.—I am, etc.,  
E. B. WAGGETT.  
Charing Cross Hospital, July 2nd.

#### THE EPILEPSIES.

SIR,—Dr. Kinnier Wilson, in his lecture on the epilepsies (July 3rd, p. 1), refers to the evidence for and against the causal factor being anoxaemia due to temporary failure of cerebral circulation; he points out certain difficulties in the way of accepting this theory, although at present there is no better. It is significant that he records the occurrence of hallucinations resembling an aura in persons half-drowned, half-hanged, or half-suffocated. In all these conditions there is oxygen deficiency in the tissues.

Failure of the circulation and anoxaemia are only two of the many ways in which the processes of oxidation in the cell may be hindered; thus there may be a normal supply of oxygen in the arterial blood reaching the neighbourhood of the cell, and yet the cell may not be able to use it normally; this occurs in cyanide poisoning.

As a result of recent physiological experiments dealing with tissue oxygen tension, tetany, and convulsions, I came to the conclusion that tetany and convulsions, however produced, were due to interference with oxidation in the nerve cell and that the violent contractions in tetany and convulsions were purposeful—that is, to increase the oxygen tension in the cells. I found that muscular contraction, however produced (for example, by exercise or by convulsions), caused a marked rise of oxygen tension in the tissues.

I would suggest tentatively that similar conditions exist in the epilepsies—that is, they are due to interference with cell oxidation processes—and that the violent muscular contractions represent an effort on the part of the body to remedy the defects.—I am, etc.,  
J. ARGYLL CAMPBELL.  
London, N.W.3, July 3rd.

#### ELECTRICAL TREATMENT OF TIC-DOULOUREUX AND ANGINA.

SIR,—Dr. Turrell's success in the treatment of tic douloureux is confirmed by my own experience. I have treated with gratifying results several cases, the most striking being that of a lady, aged 50, who had suffered on and off for twenty years; during the last three years her complaint had grown steadily worse until her condition was pitiable. She came to me for treatment at the beginning of November, 1924. She was in almost constant pain, paroxysms being set up by almost any movement or attempts to masticate. Practically every treatment had been tried and surgical measures were suggested, but advised against by the surgeon consultant. I treated her with ionization, thrice weekly, for a month. From the commencement she began to respond and the attacks diminished in frequency and severity rapidly until at the end of twelve treatments she was quite free from pain. She remained free for two weeks, when she thought she felt mild signs of the pain returning, so she thought she treatments. Since then she has had no return of pain and is quite free in spite of the fact that all through last winter she went out in the coldest weather, which had not happened for years previously: Other cases have shown equally good results.

Dr. Basil Hughes appeals for a communication on the treatment of angina, and I am pleased to give my experience in these cases. Although I have had the opportunity of treating only six, the results have been so encouraging that I consider the treatment has great possibilities. These cases have been treated with diathermy—through the heart, placing one electrode over the cordial area, and the other on the back.

The first case was a man aged 64, with symptoms of two years' standing, increasing in severity and frequency until he came to me in May, 1924. At that time he was averaging eleven or twelve attacks a day. He was unable to lie down, but slept propped upright with pillows. He had consulted Dr. John Hey of Liverpool, who suggested that diathermy should be tried. He received three treatments a week for six weeks. After fortnight's treatment he was much improved and could sleep lying down and walk better, and the attacks diminished until at the end of a month he only had occasional mild attacks. After six weeks' treatment his attacks had ceased. I saw him again in December, 1924, and he was still free from attacks and has remained so until recently, when I have lost sight of him. Up till then he was living the normal life of a man of his age.

I have treated three other severe cases since, with equally good results, and two milder cases. The one failure was a gentleman of 74, who improved so much after two weeks' treatment that he gave it up for five weeks and refused to attend regularly, having six more treatments at intervals. Recently he had a recurrence and died, but the treatment was incomplete and very unsatisfactory, and this in no way negatives the success in those cases who received sufficient treatment. These results certainly justify an extended trial of this method, which is convenient, simple, and, in experienced hands, absolutely safe.—I am, etc.,

JOHN N. DYSON, M.R.C.S., L.R.C.P.

Southport, Lancs, July 4th.

#### A PLEA FOR OPHTHALMIC EXAMINATION IN INFANCY.

SIR,—Many common refractive errors and visual defects are either congenital (that is, present at birth and of no earlier origin than conception) or hereditary (that is, reproduced from ascendants during development or life). Some improve. A few remain stationary. Others, from inherent tendency or adverse environment, deteriorate. For lack of fostering in infancy, visual faculties may fail to develop. Many older children find their preparation for attractive careers arrested, owing to processes which might have been foreseen, if not prevented.

So dimly are these facts realized by the laity that an infant's eyes are rarely examined unless there is some glaring defect. Damage is often done before intervention is possible by public bodies, which have shouldered enormous burdens in respect of the treatment of visual defects. An observant family practitioner is in a unique position with regard to those children he has known from infancy; is it not his duty to initiate, not later than the third year, such steps for the preservation of vision as experience dictates?

Congenital distortion of the cornea (astigmatism) interferes with the development of the form sense. Children with over three dioptries of astigmatism rarely see well until glasses have been worn for some time. The first indication that a high degree of astigmatism is present may be the onset of nystagmus. Hypermetropia is also congenital, and as sustained accommodation without convergence is fatiguing an illness such as measles may be followed by squint. Squint impairs children's prospects, gives anxiety to parents, and causes loss to school authorities whose grants are based on attendances. The vision of a squinting eye deteriorates and nature adapts structure to function in the extraocular muscles, hence the treatment is tedious. It is possible to recognize a predisposition to squint, and to cultivate binocular vision by prescribing glasses and simple fusion exercises. If one eye has already become lazy it may be stimulated by applying atropine to the other. By increasing susceptibility to external affections, hypermetropia predisposes to the formation of superficial opacities, which impair vision more commonly than all the diseases of the deeper structures put together.

Myopia doubtless arises from strain imposed during education, but the process is cumulative—spread over successive generations. Consider the following case.

A girl, aged 9, whose father and two sisters were short-sighted, complained on returning from school of having lost the sight of one eye. Both eyes were myopic and there was a retinal detachment in the left. After a period of rest the child was sent to live with relatives in the country, and received oral instruction only. Two years later the retina was completely reattached, but vision was permanently impaired.

What of the next generation? Surely their eyes should be kept under observation from infancy. Cataract in infancy is often a familial defect. In advanced cases the longer operation is postponed after the tenth month the greater the danger of permanent nystagmus. The severity of interstitial keratitis may be reduced by treatment, the need for which can often be recognized in infancy. Ophthalmic examination at any period may throw light on obscure disturbances of general health.

Eugenic intervention is impracticable; moreover, defects would continue to arise from the same causes as have operated in the past. When the late W. E. Forster, introducing compulsory education in the House of Commons,

observed, "We must not forget that in trying to do good it is possible to do harm," he was concerned mainly with spiritual dangers, but his warning should also be applied to physical conditions. It is as important to provide a system of education whereby good vision may be protected as to provide special institutions to which those with bad vision may be relegated.

Ophthalmic examinations under a cycloplegic should be instituted in infancy and repeated at regular intervals; no defects would be found in the majority, but in the minority such conditions as would result in modifications of the normal curriculum and the cultivation and preservation of vision by various means, including prescription of glasses, medical treatment, or, in rare instances, surgical intervention.

Some effect may be expected in this generation, but it is only among our children's children that the full measure of success can be achieved. We ought not to abate our efforts on this account.—I am, etc.,

W. OLIVER LODGE.

Bradford, March 14th.

#### "ATOPHAN DERIVATIVES IN RHEUMATISM."

SIR,—Dr. W. Langdon Brown's letter in your issue of July 3rd (p. 37), calling attention to the toxicity of atophan derivatives, is of great importance. I very often prescribe these drugs, and always with caution, because of the slight or moderate toxic symptoms they not infrequently produce. But I have had three cases of severe poisoning going on to the development of jaundice, and in one case associated with repeated vomiting. These symptoms may arise in spite of the simultaneous administration of sodium bicarbonate, and they are not the result of large doses. In my experience they are sometimes due to a personal idiosyncrasy, for one of these patients developed the symptoms on two separate occasions, and on the second occasion after taking only one or at most two half-gram tablets. Another patient never took more than ten tablets in a week and developed the symptoms of hepatic disturbance after taking only thirty tablets. Further, in my experience no one preparation on the market is less likely than another to cause these toxic symptoms.—I am, etc.,

London, N.W.1, July 2nd.

GEOFFREY EVANS.

SIR,—Dr. Langdon Brown, in your issue of July 3rd, rightly emphasizes the need for caution in the administration to patients of atophan derivatives. He mentions two fatal cases of toxic jaundice following the use of atoquinol. In the *BRITISH MEDICAL JOURNAL* (1923, i, p. 148) I recorded a case in which the ingestion of  $\frac{7}{8}$  grains of atophan three times daily was followed by intense urticaria and subsequent jaundice. K. Schroeder had previously pointed out the liability of atophan derivatives to give rise to toxic symptoms, such as gastro-intestinal disturbance, urticaria, and albuminuria, but so far as I am aware jaundice had not been reported.—I am, etc.,

London, W.1, July 6th.

C. WORSTER-DROUGHT, M.D.

\* \* We have received a communication from Messrs. Schering, Ltd., regarding Dr. Langdon Brown's reference to two fatal cases of toxic jaundice following the use of atoquinol. They state that atoquinol is not an atophan derivative, since atophan is a trade name applicable only to products emanating from the Schering Laboratories. They add that atophanyl is a solution of the sodium salts of phenylechinolin-carbonic acid combined with sodium salicylate, whereas atoquinol is described as allyl-phenylechinolin ester; the two preparations, therefore, differ materially.

#### HISTORY OF MEDICINE.

SIR,—Your issue of June 26th (SUPPLEMENT, p. 244) contains notice of a motion by the Brighton Division to be made at the Annual Representative Meeting that the Council should be instructed to consider the desirability of instituting a Section on the History of Medicine at the Annual Meetings of the British Medical Association. The same project has presented itself as desirable to the Edinburgh and Leith Division, and this Division some time ago

forwarded a recommendation expressing a desire that a Section on the History of Medicine should be formed for the meeting which is to take place at Edinburgh in July, 1927. It seems to be particularly appropriate that the Section should be initiated at the Edinburgh meeting, seeing that this medical school was, I believe, the first in Great Britain to provide for instruction of medical students in the history of their profession by instituting a lectureship on history of medicine in 1908. The fact that considerably over 1,000 students have attended this optional course at Edinburgh since its commencement is sufficient evidence of the increasing attention which this subject is now receiving in Great Britain. If other Divisions will follow the lead of Brighton and press for the formation of this Section it will no doubt come into being and prove a much appreciated feature of the Annual Meetings of the Association.—I am, etc.,

JOHN D. COMRIE,  
Chairman, Edinburgh and Leith Division.

Edinburgh, June 30th.

### APPEALS FROM THE GENERAL MEDICAL COUNCIL.

SIR,—It is significant that two Divisions of the British Medical Association—Hastings and Bournemouth—have given notices of motion for the forthcoming Annual Representative Meeting relating to the right of appeal from disciplinary decisions of the General Medical Council.

It is hoped that this subject will receive due consideration by the Representative Body exclusively upon its merits, and entirely unprejudiced by any recent clamour of the lay press, or the public, or certain malcontents within the profession, however misinformed or well informed. The standard of professional ethics has always been jealously guarded by the General Medical Council, and rightly so—indeed, it may be granted at once that the Council exhibits a constant endeavour to perform its duties impartially and with every indication of care and good judgement.

Nevertheless the fact remains that, functioning as a domestic tribunal only, and as a court of first instance, from which no appeal lies, it is thus quite remote from modern conceptions of the administration of justice, which latter are characterized by the fullest protection for the claims of the accused.

Take, for example, those cases of alleged misconduct in which the General Medical Council directs an inquiry, though there is an absence of any outside complainant: here we have the anomalous position of the Council acting as prosecutor and judge, a condition of affairs certainly alien to British ideas of justice; and yet under existing conditions no higher court possesses any jurisdiction to interfere. In the legal profession a right of appeal lies to the barrister who has been disbarred, as also to the solicitor who has been struck off the roll; *a fortiori* the claim of the medical profession, for surely a medical tribunal can scarcely be considered so competent an authority as a legal in determining points of law, and the value of evidence, its relevancy, competency, admissibility, or weight. Such intricate and involved questions in the ordinary courts are the province of an experienced judge to determine and direct.

It is conceivable that the Council might periodically be tempted in its zeal to exceed the bounds of wisdom and justice in placing members' liabilities much beyond those of the general public, and the very existence of an appeal tribunal would certainly exert a salutary effect. The Court of Criminal Appeal, for example, was created in 1907, in order to confer the same rights in criminal as in civil offences, and it has amply vindicated and enhanced the soundness of this principle of appeal in cases of alleged miscarriage of justice in the lower court.

In the Memorandum of Evidence placed by the British Medical Association before the Royal Commission on National Health Insurance (vide BRITISH MEDICAL JOURNAL, SUPPLEMENT, February 28th, 1925, para. 40, clauses 3, 4, and 5) it is laid down with reference to conduct of practitioners detrimental to the service, or giving false certificates, that appeal to the courts should be possible, and, in the case of proposed removal from the service, a further right of appeal. With such a recent

precedent embodying this principle in disciplinary procedures connected with national health insurance, the Council of the Association will only be acting consistently in demanding application of the same principle to decisions of the General Medical Council, especially since the penalty involved, of possible erasure from the *Register* altogether, is so much more severe.

After all, the practitioner we ought to safeguard is not the one persistently guilty of misconduct; but the honest man of integrity and good character, who has committed some foolish error of judgement perhaps, or offended unwittingly and unintentionally; the former will not in the least object to removal from the *Register*—indeed, he will probably enjoy being a free lance entirely, and certainly will not be likely to seek any appeal.

An excellent case might be presented for the Hastings motion (omitting the words "if and when"), which also suggests a general revision of the whole status, constitution, and disciplinary powers of the General Medical Council. But if the Representative Body is not disposed to support this at the moment, it should at least recommend the Bournemouth motion, which is concerned with the right of appeal only.—I am, etc.,

Bournemouth, July 3rd.

WALTER ASTEN.

### OBSTETRICS IN GENERAL PRACTICE.

SIR,—Professor J. M. Munro Kerr of Glasgow University, under guise of an address on preventive medicine as applied to obstetrics (June 12th, p. 977), launched what really amounted to an attack on the general practitioners of these islands. Among his audience were probably the sons and daughters of general practitioners, and for these young people to have to hear it said that their fathers sometimes conducted midwifery in houses where "every sense of decency is violated," and "whose hands are often imperfectly cleansed and who seldom wear rubber gloves," must, to say the least, have been disconcerting. Perhaps it is merely the professor's method of encouraging his students to wash their hands!

Professor Kerr said that: (1) "Puerperal infection can be prevented by special preparation of patient, surgeon, and nurses," yet, in the recent annual report of the Coombe Lying-in Hospital (see BRITISH MEDICAL JOURNAL, June 19th, p. 1059) the statement appears that among the cases of puerperal sepsis that occurred twenty-four of these had had no vaginal examination, no laceration of perineum, and no operative intervention whatsoever, and all of these, no doubt, had been suitably prepared.

(2) Cases of sepsis occurring in maternity hospitals are due to "autogenous infection" (blessed words!) or to some prior infection. Might not the general practitioner, with equal justice, be allowed similar pleading when accused of causing sepsis?

(3) "Because a confinement upsets the rest of the work of a busy general practitioner he is inclined to hasten the delivery." I can assure Professor Kerr that if he and others like him had their way the general practitioner would soon cease to be busy, unless, indeed, filling up forms for the medical officer of health.

(4) Amongst "remedial measures" he advises "rubber gloves for midwives and nurses." This sounds childish, and one wonders how long these same rubber gloves would stay sterile in some of the back streets of our large cities, where mostly midwives work.

(5) Again (para. h), "It is little short of a disgrace that at the present day the student on graduation is unfitted for the practice of midwifery." Surely a libel on these young men and women who qualify from our medical schools.

In your review, Sir, of this lecture you strike the nail on the head when you suggest that an improvement in housing conditions is much more likely to lead to a diminution of puerperal morbidity, and so would say any man in touch with the realities of the situation.

It is a pity, though, that the utterances of professors should bring discredit—as they are certain to do—on a large body of hard-working men endeavouring to do their duty in difficult circumstances.—I am, etc.,

VINCENT P. NORMAN, M.D. Durh.,

Bradford, Yorks, June 28th.

F.R.C.S.E.D.

## Obituary.

**JOHN THOMSON, M.D., F.R.C.P. ED. AND LOND., LL.D.,**  
Consulting Physician to the Royal Hospital for Sick Children,  
Edinburgh.

THE announcement of the death of Dr. John Thomson of Edinburgh has caused profound regret to a large number of friends and old pupils, for his qualities had endeared him to everyone with whom he came in contact. His health had been failing for over a year and he had been compelled considerably to curtail his usual activity. He died on July 2nd at his house in Edinburgh.

John Thomson was the son of Mr. Thomas Thomson, W.S., of Edinburgh, and was born in that city in 1856. He received his early education at the Edinburgh Academy, and then entered the University of Edinburgh, where he graduated M.B., C.M. in 1881. During the winter of 1881-82 he was resident to Professor Annandale, and in the following winter house-physician to Sir Thomas Fraser. He subsequently proceeded for a course of post-graduate study to Berlin and Vienna, and became senior resident in the Hospital for Sick Children, Great Ormond Street, London, which gave him mind a definite bent towards the study of children's diseases. In 1887 he became a Member of the Royal College of Physicians of Edinburgh, and was elected a Fellow in 1888. In 1891 he took the degree of M.D. of Edinburgh University, and at a subsequent date, on retiring from the post of clinical lecturer on diseases of children to the University, the honorary degree of LL.D. was conferred upon him. Dr. Thomson's eminence in the subject to which he had devoted his professional life was recognized by the Royal College of Physicians of London, who this year created him a Fellow under the special by-law which permits the election of persons not members of the College who, in the opinion of the Council, have distinguished themselves in any branch of the science or practice of medicine.

Dr. Thomson was a member of the Edinburgh and Leith Division of the British Medical Association. He had filled the offices of secretary, vice-president, and president respectively of the Section of Diseases of Children at the Annual Meetings of the Association in 1898 at Edinburgh, in 1900 at Ipswich, and in 1914 at Aberdeen.

His outstanding position as an authority on various aspects of diseases of childhood was recognized by his appointment to the staff of the Royal Hospital for Sick Children, Edinburgh, to which, on his retirement, he was made consulting physician, and to be university lecturer on the diseases of children. He was also consulting physician to the Royal National Institution for Mentally Defective Children at Larbert, and an honorary member of the American Pediatric Society.

His principal published work, to the composition of which he had brought an immense amount of thought and study, was the *Guide to the Clinical Study and Treatment of Sick Children*. This appeared first as a small textbook for practitioners and senior students in the year 1898, when much less attention was paid to this department of medicine than it receives at the present time. By 1908, a second edition was required, when the book had reached twice the size of the original volume, and when the third edition appeared in 1921 it had developed into a very comprehensive manual. The fourth edition was completed towards the end of 1925. Thomson was, before all things, a bedside student, and his book, the fourth edition of which was translated into French and Spanish, dealt mainly with those aspects of diseases which are peculiar to childhood or show characteristic differences when they occur in early life; it was a most valuable contribution

to clinical medicine, partly because of the simplicity of its style and partly because it is a record of personal experience and close individual bedside study. Many other observations on subjects connected with diseases of children issued from his pen. One of his early works was a translation of Hensch's *Lectures on Children's Diseases*, for the New Sydenham Society. *Congenital Obliteration of the Bile Ducts*, a monograph which appeared in 1892, was a record of original observations which later came to be recognized as of great importance. His interest in the condition of mental defect in children was manifested by a clinic which he conducted for many years for children suffering from mental defect, and which was of very great value to the poorer classes of the community. Articles on infantilism, congenital stridor, and many other subjects were contributed to various medical journals and systems of medicine and of diseases of children, and each of these is of permanent value for the record of acute clinical observation that it contains.

Nothing, perhaps, better revealed John Thomson's character, his knowledge, and his sympathy, than the little book he wrote three years ago "for the mothers of babies who are long in learning to behave like other children of their age." He called it *Opening Doors*, and, as we said of it at the time, it was pervaded by that indefinable charm we find in a work of art and could scarcely hope to discover in a book of medical advice. Every line revealed his insight into the mother's feelings. He not only told her how to strive to open the doors of her child's mind, but gave her comfort and encouragement as well. Though the advice was couched in simple language, it was given by a man with a profound knowledge of children. He interested himself also in physical defects, and was one of the principal founders of the Edinburgh Crippled Children's Aid Society.

It is chiefly as a skilful practitioner, however, that Dr. Thomson's name and personality will live among those who came into personal contact with him. He was, all his life, a sedulous taker of notes on cases, and he has been frequently known, at meetings for medical discussion, to produce a volume of closely written notes bearing on some case under discussion, and to describe in detail the original cause of the malady as noted by him during the patient's childhood ten or twenty years previously. Every call upon his time and his professional skill was answered with care and punctuality. He always found ample time to give to those who needed his skill, whether the patient was rich or poor. In him great ability was combined with a devotion to the advancement of medical knowledge on its clinical side, and few have been more respected for their painstaking labours or held in greater affection by their patients than was Dr. John Thomson.

In 1887 Dr. Thomson had married Isabel MacPhail, daughter of the Rev. Mr. MacPhail of Benbecula, by whom he is survived, as well as by three sons, of whom one is a member of the medical profession, and by two daughters. A funeral service was held in St. Andrew's U.F. Church, Edinburgh, on Monday, July 5th, and the interment took place at the Dean Cemetery in the presence of a large gathering, at which the medical profession was largely represented.

In response to our request, Dr. G. F. STILL, physician to the Hospital for Sick Children, Great Ormond Street, and professor of diseases of children at King's College, has sent us the following tribute to Dr. Thomson's memory:

With the passing of John Thomson of Edinburgh, British medicine, and, indeed, medicine the world over, is the poorer. In the particular department of medicine he had

DR. JOHN THOMSON.

(Photograph by Swan Watson, Edinburgh.)

taken for his own Thomson's influence was world-wide; his writings were known and read, not only in English-speaking countries, but in some of those parts of Europe where the work of British physicians often receives little attention. To the medical student of to-day Dr. John Thomson is probably best known as the writer of a book on disease in children, which, under the title *Guide to Clinical Study and Treatment of Sick Children*, appeared first in 1893, and, in much enlarged form, reached its fourth edition last year. Unique, however, as that book is in its excellence, it was not the source of Dr. Thomson's authority. He was well known and already regarded as an authority upon disease in children before its appearance. His writings on congenital hypertrophy of the pylorus, and on pyelitis in infants, had drawn general attention to affections which, although previously described, were still unknown to most medical men. One of his earlier publications, in 1892, was a monograph on congenital obliteration of the bile ducts, a careful study, in which, as in all his writings, he showed a wide familiarity with the work of other observers in this country and abroad. He was greatly interested in mentally deficient children, and by his writings, accompanied as they usually were by admirable photographs, he did much to familiarize the profession with the appearances of mental defect in the infant. To those who knew Thomson his writings were the more valuable because of that unswerving truthfulness in statement which was one of his characteristics. In his speech, as in his writings, he was minutely accurate, and it was perhaps partly the constant effort at exact accuracy which gave a certain slowness and hesitancy to his speech at times.

In his later years there came increasing recognition of his services to the study of disease in children. He was made an honorary member of the American Pediatric Society, and also of the Canadian Society for the Study of Diseases of Children; the University of Edinburgh conferred the honorary degree of LL.D. upon him, and the Royal College of Physicians of London elected him a Fellow. But Thomson's ambitions were not for place or position, but for the service of others; for years it was his hope to write something that might be a help to the mothers of mentally defective babies in their task of training these children, and the outcome of his observations over many years was a little booklet called *Opening Doors*; it is worded with wonderful simplicity and in such a way as to avoid mention anywhere of mental deficiency, for fear lest the mother should be discouraged thereby. This was his last publication, and it was a great satisfaction to him when, some months ago, symptoms of serious illness began to threaten him, that he had accomplished his wish. Thomson's supposed difficulty had arisen as to the right course between two practitioners, Thomson, who was appealed to, replied that he did not think there was any real difficulty if the simple course were adopted of doing what one would wish done to oneself. This was the spirit of his life, and accounted for his loveliness. For lovable he was, and there was a gentleness with him which won the confidence of children. Alas! that he is gone from us; he will be missed indeed.

"Farewell, kind heart! and if there be  
In that unshored immensity  
Child-angels, they will welcome thee."

We owe to Dr. LEONARD FINDLAY, Professor of Pediatrics in the University of Glasgow, the following estimate of Thomson's eminence as a clinical investigator and teacher: Through the death of John Thomson medicine, and especially that branch which deals with the diseases of children, has lost one of her greatest ornaments. For many years he has kept alight the torch of British pediatrics, and has made Edinburgh a Mecca for all students in that field of medical science. His was a name that was known in all corners of the earth where diseases of children are studied. The offering of a personal tribute to John Thomson gives an opportunity for the opening of the floodgates of sorrow at the loss of one of the greatest influences in the life of the present writer.

To know and to possess the friendship of John Thomson

was a great privilege. I well recall the first time that I met him. It was some fourteen years ago when, having heard that I purposed taking up the special study of diseases of children, he sought me out during the course of a medical meeting to give me good advice and words of encouragement. This was a most characteristic act on his part, for he was a true missionary, and was always searching for recruits for pediatrics. By his innate gentleness and charity and keen desire to help all the younger workers as true and faithful disciples. He seemed specially fond of the young worker just as he was of the young patient. He had the gift of mingling praise and criticism in such a proportion as to get the best out of everybody. Quite recently he was in great part responsible for instituting a clinical club comprising those interested in pediatrics in Scotland, and though he was much the eldest of the members he was the mainstay and director of our energies. It is this great gift which Thomson had for associating with the younger generation which gives us some comfort at this time, since we know that his great influence will still live and be perpetuated.

Thomson was a true physician. Perhaps this aspect of his character was best exemplified in his work among mentally defective children, which during his later years was undoubtedly nearest his heart. Here he laboured for years developing educational methods for the betterment of these helpless patients and dispensing comfort and encouragement to their parents. I think that of all his work this was the part of which he was most proud, if one could over speak of Thomson, of course, was a great clinician, and done. John Thomson, of vision and ripe experience were at the bedside his acuity of vision and ripe experience were an inspiration. Though not a laboratory man himself, he appreciated the great help that might accrue from this side and never lost an opportunity of becoming acquainted first-hand with such work. He was a wonderfully keen observer, and had the faculty of correlating his clinical observations with phenomena in other branches of medical science.

Never was there a man who had a finer nature. His charity and humility made him the most beloved of men. Thomson never spoke ill of anyone, and no one, I am sure has ever heard anyone speak ill of him. One could spend the whole evening in his company discussing many branches of medicine, and often those fields which he had made specially his own, and the work of others who held opinions diametrically opposed to his, without ever hearing from him anything but careful consideration of and praise for their efforts to solve a problem. Though he believed strongly in his own views, he was not infatuated with them, and always admitted the possibility of other explanations. He was of a most equable disposition, and never showed the least impatience while discussing views which quite apparently he could not believe to be true. It was from associations such as these that one learnt to appreciate the bigness of his heart and mind, and it is the memory of such associations which will bring home to his friends the great loss they have sustained.

We are indebted to Professor LORRAIN SMITH, Professor of Pathology in the University of Edinburgh, for the following tribute to his friend's memory:

In the death of Dr. John Thomson the Edinburgh Medical School has lost one of its leaders, a physician of high distinction, a teacher and colleague universally beloved, and a man who had supported and guided many movements for the betterment of the community. His personality drew to him a band of workers in his own and neighbouring fields of medicine, some of them ripe in experience like himself, who were eager to hear his criticism of their work, many of them students and disciples anxious to follow the teaching he gave. He won the hearts of all, and each carried away something of his enthusiasm and insight.

Though he had wide interests he concentrated his energies on clinical medicine, and one of the great lessons of his teaching is to be learned from his method of work. He held that the clinical observer should above all seek opportunities for wide experience. The man who desires

to obtain proficiency in clinical medicine must study multitudes of cases, so that his judgement in diagnosis and prognosis may be sure. At the same time, the physician must keep abreast of the advances of medicine in all fields, and he must be ready to apply in his practice the results of laboratory investigation. The ideal Dr. Thomson cherished was constant study and endeavour to widen experience, and he would point out that too often men cover up their deficiency in real medicine by a display of kindness and consideration for their patients. This appearance of virtue he utterly condemned.

In his early years he was appointed on the staff of the New Town Dispensary. In that office he found the opportunity for clinical study which he desired. The clinic in diseases of children held by him drew patients in large numbers. Mere numbers, however, did not satisfy him, and his investigations carried him far into pathology and therapeutics as well as anatomy and physiology. He often recalled the time he had spent in the dispensary, and he seemed to regard this as the most fruitful period of his professional life. When wards in the Royal Hospital for Sick Children were put in his charge, his work in them was a continuation of what he had begun in the dispensary. His work in the district was a demonstration of scientific zeal and enterprise. While he was working on the treatment of diseases of the thyroid gland I had the good fortune to accompany him on his visits in the district, and can never forget this great investigation, carried out in circumstances which might have been held to make accurate observations impossible.

In this way he attacked many problems in medicine, and contributed to them all. He had a special interest in the subject of mental deficiency, and at the Children's Hospital he held for many years a clinic in the subject. To advance the knowledge of this very obscure branch of medicine was a very characteristic interest. His purpose was to study the conditions of failure in mental and bodily development in all its phases, and to give guidance to the mothers of the patients. He was a pioneer in this method of dealing with the subject, and he was the first to include in his care of these difficult patients the necessary instruction of the parents.

I have referred only to his professional work, but in the background of his life there were many other interests. He was an angler who had a sportsman's acquaintance with the streams and lochs of his native country. He was a reader of many kinds of books. At one time his interest led him into the study of old French poetry. Lately he attended with great enjoyment the meetings of the English Association, and to his intimate friends he would reveal a sensitive spirit of literary appreciation and criticism. He had, above all, broad sympathies. He was accessible to all, and the serious attention he gave to what was put before him would sometimes embarrass the careless advocate of an ill considered opinion. Every form of sincere human endeavour after truth, and the teaching of the past as well as the present, appealed to him. Nothing narrow in regard to religion, or literature, or any human activity found a place in his conception of life.

#### W. H. CLAYTON-GREENE, C.B.E., M.B., F.R.C.S.,

Formerly Surgeon and Lecturer on Surgery, St. Mary's Hospital.

As briefly announced in our last issue, the death of Mr. William Henry Clayton-Greene occurred on June 30th, at his home in Guernsey, whither he had retired nearly two years ago. He started his medical career at Cambridge, and having won an open scholarship to St. Mary's Hospital in 1898, took the M.R.C.S., L.R.C.P. in 1900, and the M.B., B.Chir.Cantab., and the F.R.C.S.Eng. in 1901. In the following year he was appointed surgical registrar to St. Mary's Hospital, and from then onwards he remained connected with it till the date of his retirement. He became surgeon to out-patients in 1905, and full surgeon in 1911. In addition, he was on the surgical staff of the French Hospital from 1903 to 1918, and of the Hampstead General Hospital from 1907 to 1910.

On the outbreak of war he joined the staff of Lord Tredegar's steam yacht *Liberty*, specially converted into

a hospital ship; but it was soon seen that hospital ships with the fleet would have little value, and he returned to London. He was on the Admiralty emergency list of surgeons willing to go at short notice to any ports where large numbers of naval wounded were expected, and later, in 1915, joined the surgical staff of King George V Hospital, under Colonel (later Major-General Sir) Murray Irwin, A.M.S. Later, when the Great Central Hotel was converted into the Prince of Wales's Hospital for Officers, he was on the active surgical staff there. After the war he became consulting surgeon to the North Herts and South Bedfordshire Hospital, and honorary surgeon to the Radium Institute, in the activities of which he always took a keen and sympathetic interest.

In 1907 Mr. Clayton-Greene became dean of the Medical School of St. Mary's Hospital, and continued in that office for four years. He was an examiner in surgery for the Conjoint Board, the Universities of London and Cambridge, and an examiner in anatomy in the Primary Examination for the Fellowship of the Royal College of Surgeons. His best known writings include the editing of *Pye's Surgical Handicraft*, and the section on diseases of the tongue in *Choyce's System of Surgery*.

Mr. Clayton-Greene gained a great reputation both as a surgeon and as a teacher. As a surgeon he was a peculiarly acute observer of details, and thereby a good diagnostician; he possessed a brilliant technique, was quick, neat, and eminently safe and sure. Although he wrote little, and attended scientific meetings but rarely, his name was known widely outside London, and, indeed, abroad as well. As a teacher he was in the direct line following such great men as Edmund Owen and Herbert Paget, and it was not difficult to trace their influence on his methods. From his earliest days at St. Mary's he rapidly gained an ascendancy among students which he never lost. There will be many who will never forget their experiences when in that select band—"the front row"—nor incidentally will ever forget the things he taught them. His teaching was so direct, so forceful, so devoid of unnecessary or confusing description, that it remains with many of his students as clear to-day as when they heard it years ago. In 1921, when the system of clinical units was in its infancy, the authorities of St. Mary's Hospital started, on their own initiative, and without outside support, a medical and a surgical unit. Of the latter Mr. Clayton-Greene took charge for one probationary year, during which its success was emphatically demonstrated and his great gifts as a teacher given full opportunity.

To those who knew him intimately he revealed a charming personality, a loyalty which nothing could shake, and a devotion to little children which was probably the strongest—though the most unsuspected—thing about him. He certainly did not suffer fools gladly, and the lazy and the inefficient dresser was sent about his business in a manner which left him no illusions about the work during the period of his office. One of the strongest traits of his character was punctuality; he could always be relied upon to be just ahead of time, and so skilfully did he order his doings that even the uncertainties of surgical practice rarely made him deviate from his announced time. To serve him as a dresser, a house-surgeon, or as his assistant was the most stimulating experience, for he set himself such a high standard that it was almost impossible not to try in some small way to follow that standard also; and those who did so may have had a very strenuous time, but they enjoyed every moment of it.

During the latter part of the war he pricked his finger on a spicule of bone, while operating on a bad war wound. He went down with a terrible streptococcal infection, and in turn his life, his arm, his forearm, and his finger were despaired of. He saved them all. He suffered also from an unrecognized diphtheria, and had a transitory typical diphtheritic palsy. These experiences, in addition to very hard work, left their mark upon him. For many reasons he came to the conclusion in 1924 that he would prefer to retire. There can be little doubt that at the age of 49, with an already high position in the surgical world of this country, he had everything at his feet; and yet he preferred to go, preferred to retire when young enough to enjoy his possessions. He went to live in Guernsey, where,

in lovely surroundings, he made surgery his hobby and his recreation in life, and did just enough to maintain his interest. His illness was of less than a week's duration, and at the early age of 51 he passed peacefully away.

R. M. H.-J.

We are indebted to another friend and former colleague for the following personal appreciation:

The sudden death of Mr. Clayton-Greene has come as a great shock to a large circle of friends, both in the medical profession and among the general public. No rumour of his illness had reached us from Guernsey, and the paragraphs appearing in only one or two morning papers on July 3rd were all the more stunning because they found his friends quite unprepared. Less than two years ago he surprised us all by giving up prospects which, to a man with ordinary ambitions, must have seemed the brightest; but "Clayton" was never a man with ordinary ambitions, and it was a real desire for quietness and leisure that took him away from the turmoil of London to the peace of Guernsey.

It is nearly thirty years since I first met Clayton-Greene, and every year our friendship has only served to deepen and confirm my first impressions of him. One could not be with him for more than a very short time without realizing that one had to deal with a man of very marked individuality and of more than average ability. Others can speak of his technical skill as a surgeon, of his wonderful teaching powers, of his intimate and detailed knowledge of everything which bore on the science of his profession. Only to those who lived with him was it given to know what anxious thought he gave all the time to every case under his care, and how much of his life he gave to his patients. To be house-surgeon to Clayton-Greene was the ambition of every first-class student, and no better training in efficient workmanship could be found. True, he did not suffer fools gladly, and he was unsparing in his condemnation of any slackness or inefficiency which in any way endangered the success of an operation or militated against the comfort of a patient.

There have been great surgeons who have been able to put completely out of their minds any case except when it was immediately before them, who, when they have done all that their skill can do, can go away with an easy mind. Others equally great seem to have their cases always before their eyes and always in their minds, and it was to this second class that Clayton-Greene belonged. As his fame grew he began to get an unduly large proportion of cases of great severity, and there is little doubt that the strain of dealing with these cases was the main cause of his giving up his surgical practice in London.

In little things he could be brusque and offhand in manner, but in the more serious matters of life he had a depth and sincerity of feeling that, once experienced, formed an unbreakable bond of friendship and love. Few men have more deeply impressed themselves on their generation, and seldom has a man been so much missed as "Clayton" has been at St. Mary's. It is some consolation to know that his two years at Guernsey have been years of happiness, to know that he never regretted giving up, and to know how greatly he was loved and esteemed in the island. To his widow and children we offer our deepest sympathy in their great loss, and the knowledge that his memory will be held dear by the many colleagues, students, patients, and friends who owed so much to him and loved him so well.

JOHN MUNRO MOIR, M.D., V.D.,  
Inverness.

THE death took place at his residence in Inverness, on June 29th, of Dr. John Munro Moir, one of the oldest and most respected practitioners in the North of Scotland. Dr. Moir had been ailing for some time, but had until recently been able to do a considerable portion of his usual work. He studied in Aberdeen, taking the degrees of M.B., C.M. there in 1876, and proceeding to the degree of M.D. in 1878. He settled in practice in Inverness early in life, and became one of the leading practitioners in that city and throughout the North of Scotland.

Despite a very busy life in medical practice, his interests

were wide, and he had found leisure for many other social activities. For a time he acted as a member of the Inverness Town Council, and he took a very intimate and active interest in the work of the British Medical Association. Dr. Moir had been a member of the Association for almost fifty years, having been elected in 1878. For a number of years he acted as honorary secretary and treasurer of the Northern Counties of Scotland Branch, and the esteem in which his work for the Association was held by his fellow members was evidenced by his election as president of this Branch in 1898, an honour which was again conferred upon him in the year 1924-25. He was elected chairman of the Inverness Division in 1914, and held this post through the years of the war till 1919. His outstanding position in one of the departments of medicine to which he had paid particular attention was recognized by his election as vice-president of the Section of Medical Sociology at the Annual Meeting of the Association held in 1914 at Aberdeen. In addition to his interest in the local work of the Association, Dr. Moir played a considerable part in its central organization. Thus, he acted as representative of the Northern Counties of Scotland Branch between the years 1904 and 1907, and again from 1913 to 1918. During a great part of this time he was also a member of the Council of the Association, acting in this capacity from 1907-8 to 1910-11, and again from 1912-13 to 1917-18. The committees of the Association on which he served included the Organization, Journal, and Medico-Political Committees, and at the time of his death he had been for some years a member of the Scottish Committee. Dr. Moir was consulting surgeon to the Northern Infirmary at Inverness, honorary physician to the Northern Counties Institute for the Blind, and a medical referee under the Workmen's Compensation Act. For many years he had taken an active interest in volunteering, and held the Volunteer Decoration. On the formation of the Territorial Force his activities were transferred to this organization, and he ultimately attained the rank of lieutenant-colonel in the Territorial R.A.M.C. During the war he rendered valuable services in connexion with the work of the depot of the Cameron Highlanders at Inverness.

He will be much missed in the North of Scotland, where he was greatly respected as an energetic, unassuming, and skilful practitioner, and where his work in connexion with the organization of the medical profession was highly appreciated by his fellows.

We regret to record the sudden death, on June 20th, at his residence in Worthing, of Dr. ALLAN GORDON RUSSELL CAMERON. He was born in 1868, and was the son of Mr. Donald C. Cameron of Wakenaam, British Guiana. He received his early education at University College School, and was afterwards a student at St. Mary's Hospital. He obtained the diplomas of M.R.C.S., L.R.C.P. in 1891, and in the following year graduated M.B., B.S. at Durham University; in 1895 he took the D.P.H. of Cambridge. In 1896 he was appointed to the infectious hospitals service of the Metropolitan Asylums Board, and in 1901 was instructed by the board to make a special investigation into the subject of "return" cases of scarlet fever and diphtheria. On this important and difficult question he submitted a very valuable report, and as a result certain recommendations with a view to the attainment of a higher standard of efficiency in protecting the public from infection were made by the medical superintendents and adopted by the board. During his service under the board Dr. Cameron was granted leave for service in India in connexion with plague administration, for which he received the special thanks of the Government. In 1905 he was appointed county medical officer of health for West Sussex and chief school medical officer to the West Sussex Education Committee. In 1913 he became deputy medical officer of health and chief tuberculosis officer for the county of Durham, and held these appointments until his retirement in 1923 on account of ill health. Dr. Cameron took a prominent part in the work of the Society of Medical Officers of Health, and was an ex-president of the Northern and Southern Branches. His death will be deeply felt by his many friends, who held him in high regard for his exceptional qualities both of mind and character.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons read the Boards of Guardians (Default) Bill a second time on July 5th by 341 to 124. The Minister of Health explained that the bill had been brought forward in consequence of the policy pursued by the West Ham Board of Guardians. He repeated that the Government intended to introduce next year a general measure for reform of the Poor Law system, whereby boards of guardians would be abolished and their functions transferred to other bodies. The bill provided that the Minister of Health, when convinced that a board of guardians had exceeded its functions, could supersede them by appointed persons. On the same date the House approved the continuance for another month of the Regulations made under the Emergency Powers Act. The Report stage of the Finance Bill was commenced on July 6th, and on the following day the House considered Supplementary Estimates for expenditure consequent upon the recent general strike and the coal stoppage.

On July 6th Dr. Edgar Collis, Talbot Professor of Preventive Medicine in the Welsh National Medical School, Cardiff, addressed the Health and Housing Committee of Unionist Members of Parliament at the House of Commons. Dr. Fremantle was in the chair. Professor Collis said the coal mines were the Cinderella of public health. Health provisions underground were not made by the Government, by local authorities, or by employers, nor was there a demand among the miners for such provisions. He himself had not given evidence before the Royal Commission about this aspect of the coal problem because he did not wish to bring health regulations in mines into a political controversy. The health conditions in the mines in South Wales and Lancashire were not so good as in those of Nottinghamshire and Derbyshire. Nowhere was there a supply of drinking water underground, nor such provision for obtaining and taking food as was found in factories. He thought it would be possible to arrange a system whereby food was sent down the shaft and a place arranged where men could eat it. From the ordinary point of view the life of the miner was specially healthy, but in deep pits, with temperatures above 70°, heavy work threw an enormous strain on him, and a man might lose 10 lb. weight in a single day. Dr. Collis doubted whether in these deeper pits an increase in working hours would mean increase in output. Much absenteeism in mines was due to diseases such as rheumatism, which might not keep a surface worker away from a factory, but which made work at the face dangerous for a man who could not move quickly. The miners also had their occupational diseases, such as "beat-elbow" and "beat-knee." He alluded to the fact that miners were never taught how to do their work. By the use of the metronome and motion study a more efficient rhythm had been obtained experimentally, and men who had been taught this had been found to be still using it months afterwards.

### Coal Mines Bill.

In the course of the debates on the Coal Mines Bill some references were made to questions of health. Dr. Watts, speaking as a general practitioner who for twenty-five years had worked in an industrial and mining area of Lancashire, said that the miners' calling was the healthiest of occupations in the country—far healthier than the cotton trade; but he admitted that it was a dangerous occupation. Mr. Barr said that the returns of the Registrar-General of Births and Deaths did not support this, and Mr. Lee asked whether it was not true that only the healthiest men took up mining. Mr. Jenkins produced a miner's pay ticket which, he said, showed that the colliery doctor's payment was secured by the owners deducting the money from wages. Dr. Watts retorted that at the present time nothing could be taken from the pay of the miner in that way, because he was insured under the National Health Insurance Acts. Mr. Jenkins said that the payment of 8d. a week was in addition to that. Mr. Paling said that official returns of the Mines Department showed the number of fatal and other accidents occurring in the mines in each complete year before and after the introduction of the Eight Hours Act and the Seven Hours Act respectively, and the number of persons engaged in the mining industry during each such year. The average killed each year (after allowing for the three months off in 1921) in six years under the Seven Hours Act was 1,147. The figures were 1,407 under the Eight Hours Act, or 260 fatal accidents more per year under the Eight Hours Act than under the Seven Hours Act. Sir Arthur Steel Maitland (Minister for Labour) said that as far as the facts justified any inference of that sort, it was that always in the last hour of work there had been somewhat of an increase in the accident rate, but that increase, if anything, had been rather greater with a seven-hour day, possibly under greater pressure, than it had been with an eight-hour day. The only conclusion that could quite safely be drawn on the question of accidents was that year after year the accident rate had diminished, partly through care, partly through more appliances, partly through general overseeing. At the close of the debate Colonel Lane-Fox (Parliamentary Secretary, Mines

Department) dealt with the figures about accidents which Mr. Paling had cited. He said that during the eight-hour period the figures were certainly higher, but the end of the eight-hour period coincided with the time when stone dusting came in, and there was a marked reduction in coal dust explosions. In the first period there were 150 deaths per annum from accidents due to explosions, but during the second period there were fewer than 20. That showed that a large proportion of the accidents were due to explosions and not to fatigue or the physical condition of the men.

The bill was read a third time by 332 to 147.

### Bills.

The Report stage of the Bethlehem Hospital Bill, which had come down from the House of Lords, was taken in the Commons on June 30th.

The Royal Assent was given on June 30th to the Criminal Justice Amendment Act, Imperial War Graves Endowment Fund Act, and to several Acts confirming hospital charity schemes.

On July 6th the House of Lords read the Mines Bill a second time by 176 to 17. In the preceding debate Lord Arnold said half the miners worked in seams 4 ft. or less in height, often in very high temperatures. He contended that the miner's occupation was very unhealthy.

**Ventilation of Houses.**—Replying, on July 1st, to Commander Kenworthy, who drew attention to the sanctioning of houses with no chimneys or adequate flue outlets from the bedrooms, Mr. Chamberlain said he could not agree that efficient ventilation must be provided by chimneys or flues. Model by-laws issued by the Ministry of Health provided that adequate means of ventilation should be provided for every habitable room.

**Incidence of Venereal Diseases.**—On July 5th the Minister of Health informed Dr. Vernon Davies that he was advised that the returns from the treatment centres indicated that there had been a considerable reduction during the past five years in the incidence of venereal diseases, and particularly of syphilis, among the civilian population. One of the objects of the centres was to render the patients non-infective with a view to preventing the spread of venereal diseases, and he was advised that this part of the work of the centres had contributed specially to the decline in the incidence of these diseases. The recorded mortality from syphilis, and other conditions due to syphilis, had fallen considerably since the institution of special measures for the treatment of venereal diseases.

**Mental Defectives.**—On July 5th Sir K. Wood, in reply to Sir C. Rawson, said that he had received representations from local authorities with regard to the increase of mental defectives in the country and the increasing cost of maintaining and extending institutional treatment, but the Minister of Health was not aware of evidence to indicate that the incidence of mental defect was increasing. Though the cost of maintaining and extending institutional treatment was heavy, the Minister could not accept the suggestion that it was usually either unsatisfactory or ineffective. The Mental Deficiency Act of 1913 already provided machinery by which defectives could be segregated or placed under guardianship or supervision. The absence of sufficient institutional accommodation was hampering the operation of the Act, and local authorities had been urged to make further provision.

**Venereal Disease in the Navy.**—On July 1st Mr. Davidson informed Dr. Vernon Davies that the incidence in the navy at home and abroad of syphilis and gonorrhoea during the years 1922, 1923, and 1924 (latest figures available) was as follows:

|                             | Ratio per 1,000 sick daily. |       |       |
|-----------------------------|-----------------------------|-------|-------|
|                             | 1922.                       | 1923. | 1924. |
| Syphilis (first record) ... | 0.70                        | 0.56  | 0.53  |
| " (latest record) ...       | 1.16                        | 1.02  | 0.84  |
| Gonorrhoea (acute) ...      | 3.17                        | 2.89  | 2.68  |
| " (sequelae) ...            | 1.28                        | 1.29  | 1.23  |

He regretted that no statistics were available of the number of cases in which preventive measures were adopted.

**Invaliding from the Navy.**—Mr. Bridgeman, on June 30th, replying to Major Hore-Belisha, who asked what procedure was followed in the case of men invalided from the navy who desired to question the decision of the medical officer, said that all representations made by the rating prior to the medical survey were carefully considered by the board of survey. These and any further representations made by him or on his behalf subsequent to the invaliding were carefully investigated by the medical authorities at the Admiralty, in conjunction with the rating's medical history and with reference to conditions of his service. Any medical report which might be the basis of the complaint was referred to and taken as evidence, subject to further investigations or other evidence.

**Substitution of Margarine for Butter.**—Sir Kingsley Wood, on June 30th, in reply to Mr. Lansbury, who asked if the Minister of Health had consulted his medical advisers before recommending the West Ham Guardians to substitute margarine for butter in the dietaries prescribed for patients in the institution at Whipps Cross, said that the Minister had not recommended the West Ham guardians to make the substitution suggested. The dietary of this institution was supervised by the medical officer of the institution. With regard to the dietetic value of margarine Sir K. Wood referred to the special report on "Diet in relation to normal nutrition," issued by the Ministry in 1921.

**Areas affected by the Coal Strike.**—On July 1st the Minister of Health stated, in reply to Sir H. Brittain, that he was keeping in constant touch, through his general inspectors, with the areas affected by the coal stoppage. In reporting to him they had, at his request, paid special attention to the condition of the children. A large amount of assistance was being given by the supply of meals and other food, and there was no evidence of malnutrition of children.

**Invaliding in the Air Force.**—On July 1st Sir P. Sassoon informed Major Hore-Belisha that when an airman was dissatisfied with the decision of a board of medical officers (normally three) that his disability was not directly attributable to service, and appealed to the Air Ministry, he was asked to furnish the grounds of his appeal if not already given in his letter, and in particular any evidence additional to that considered by the board. On receipt of the information the decision of the invaliding board was reviewed in the light of all the facts and of any further evidence available, and if the case appeared to warrant it a further board would be held.

#### Notes in Brief.

Mr. Neville Chamberlain stated that a veterinary qualification, though desirable, is not essential for the examination of imported meat from the public health point of view.

The new Milk and Dairies Order will come into operation on October 1st. Its terms have been settled, and copies should be available in the course of a week or so.

On July 6th Dr. Haden Guest introduced a bill to provide for minimum rates of wages and hours of labour in industries protected from foreign competition, and it was read a first time.

The death rate per 1,000 among all labour, surface and underground, in the gold mines in the Gold Coast is approximately 8.5. No reliable figures are available as to the sickness rates.

The Committee considering the liquor control system in the Carlisle area is still taking evidence, but may consider its report in the autumn.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

At a congregation held on July 3rd the following medical degrees were conferred:

M.D.—W. V. Robinson, H. S. Souttar.  
M.Ch.—H. A. B. Whitelocke.  
B.Sc.—T. H. Sellors, R. W. A. Simmons, D. Lurie, G. H. Crisp, A. V. Clemmey, R. A. Hamilton, F. J. Sale, C. R. Croft, G. P. Thorold, H. E. Cuthbert, W. R. Wood, O. R. Tisdall, Rosa S. Wordsworth, Margaret N. Jackson, Constance I. Palfu.

### UNIVERSITY OF CAMBRIDGE.

The following candidates have been approved at the examinations indicated:

M.Ch.—T. M. Thomas  
M.B.—B. Chitt (Part I), Sur Armstrong, B. Blaxill, Elliott, R. W. B. Ellis, J. G. J. Gross, M. J. Har D. F. Lawson, R. Marul J. Morris, C. G. E. Pl Walke (Part I), cology, W. F. Cooper, R. K. De A. B. Eddowes, J. B. E. H. J. Heathcote, G. C. S. Levv-Simpson, W. H. E. Nelson, H. W. Nicholson, F. B. Parsons, L. A. Richardson, F. W. Roques, K. G. Salmon, G. Simon, R. E. Smith, A. W. Spence, R. S. Starkey, B. C. Tate, H. B. Trumper, V. B. Wiglesworth, J. G. Wigley, H. L. Wilson, F. G. Winterton, A. T. Worthington, H. R. Youngman.

### UNIVERSITY OF LIVERPOOL.

The following candidates have been approved at the examinations indicated:

M.D.—R. G. Cooke, C. W. Healer.  
M.B.—CH.B.—186 R. G. Walsley, 24 R. M. Ainsworth, 25 J. F. Galloway, 26 F. Murgatroyd. (Part II): Grace A. Austin, B. Brickman, G. E. Church, J. L. Clegg, D. Cohen, R. F. Corlett, J. C. Edwards, Elinor M. Gelling, E. H. Glynn, A. J. Goss, Dorothy H. Gough, J. Halton, D. G. Henry, B. S. Jarvis, T. A. Jermy, A. N. Jones, C. Kaufman, G. T. Krajewski, J. S. Logan, D. B. Macaulay, W. A. McCurdy, J. C. McFarland, G. McLoughlin, J. Morgan, G. W. Paton, H. E. Pearson, Mary T. Penrice, D. E. Pritchard, A. V. Russell, M. R. Sheridan, Mary A. Silcock, N. P. Slade, I. Thomas, G. D. Thompson, (Part I): E. Wallace, Kathleen M. Ward, A. K. Wilson, Nora M. Wilson. (Part II): J. G. Hattlingh, R. E. Jackson, G. W. Phillips, J. Williamson. (Part II): S. W. Adler, A. B. Anderson, T. Blezard, W. S. Brindle, H. O. Calver, A. N. Cameron, 6 J. E. Cameron, S. Canter, E. Cohen, F. R. Craddock, W. S. Creer, A. Dals, A. Dodd, T. L. Dowell, W. J. Eastwood, Lilian W. Edwards, Ruth M. Fennell, J. J. Graham, Elsie A. Griffiths, G. T. Harris, 6 E. D. Irvine, K. Jilani, R. N. Johnson, O. V. Jones, I. Koszew, 6 T. Lasker, Theresa J. Lee, J. L. Lewis, F. E. Lomas, J. McHugh, T. C. Newman, J. Pasvolsky, J. W. Pickup, E. E. Prebble, C. Rigby, N. W. Riley, G. L. Roberts, J. B. Rushton, M. Silverstone, V. J. M. Taylor, J. P. Thomas, S. L. Tunnicliffe, A. J. Walsh, E. N. Wardle, P. H. Whitaker, A. L. Williams, R. L. Wynn.  
D.P.H.—W. E. Haigh, J. E. Power, J. A. Scott, A. E. Wall.  
DIPLOMA IN TROPICAL HYGIENE.—W. J. Aitken, N. High-Peacock, T. Cullen, E. G. A. Don, H. P. Fowler, D. Lennox, A. G. Mackay, F. Oppenheimer, S. A. Talib, N. S. Turnbull.

1 First class honours.  
2 Second.  
3 Distinction.  
4 Distinction in surgery.  
5 Distinction in midwifery.  
6 Distinction in public health.  
7 Distinction in toxicology.

### UNIVERSITY OF BIRMINGHAM.

Dr. Laurence Ball, assistant to the chair of medicine and physician to Queen's Hospital, has been appointed to be joint Professor of Medicine. Professor Leonard Gamgee, M.S., F.R.C.S., has been elected the representative of the University on the General Medical Council, in succession to Sir Gilbert Barling, Bt., resigned. At a congregation held on July 3rd the following medical degrees were conferred:

M.D.—Gladys M. Evans, V. G. Williams.  
M.B.—Ch.B.—Marjorie E. Crump, A. P. Downie, Margaret L. A. Green, Joan E. Greener, G. S. Hall, A. J. Lea, Neale, de N. U. Somers, W. Summers, P. Symonds, A. C. Nellie Wilkes.

### UNIVERSITY OF LEEDS.

At a congregation of the University held on July 3rd the Vice-Chancellor conferred the following degrees:

M.D.—A. L. Taylor (with distinction), D. R. Allison, P. Rosenbloom.  
Ch.B.—A. L. Taylor (with distinction), D. R. Allison, P. Rosenbloom.  
M.B.—A. L. Taylor (with distinction), D. R. Allison, P. Rosenbloom.  
M. S. Scott, S. Silverman, J. D. Scott, A. E. W. L. White.

\* With second-class honours.

### UNIVERSITY OF DUBLIN.

At the later summer commencements in Trinity term held on June 29th the following were among the degrees conferred:

M.Ch. (honoris causa).—Sir Berkeley G. A. Moynihan.  
M.D.—F. J. O'Meara, W. B. J. Pemberton, G. F. T. Saunders, A. H. Thompson, R. B. Jackson, W. J. Powell.  
M.B.—Ch.B.—B.A.O.—G. T. L. Archer, Henrietta Armstrong, D. Blunt, H. A. Brattain, H. O. Evelyn E. Connoley, J. Craig, G. E. Dodds, E. Hadden, E. H. Hall, G. R. L. Lowther, J. G. McDowell, D. St. C. Mackenzie, M'Neilly, E. E. Malone, R. H. Mitchell, C. G. Nel, H. Nelson, H. M. Nevin, Kathleen I. Purdy, M. A. W. Roberts, E. E. Satchwell, S. Smyth, R. T. P. Tweedy, C. H. Wilson, T. F. M. M. Woods.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

#### ELECTION TO THE COUNCIL.

At a meeting of the Fellows on July 1st four Fellows were elected into the Council to fill the vacancies occasioned by the resignation of Mr. James Sherren, C.B.E., and Sir Charles Ballance, K.C.M.G., C.B., and by the retirement in rotation of Mr. Walter G. Spencer and Mr. Ernest W. Hey Groves. The result of the poll was as follows:

|                           | Votes. | Plumbers. |
|---------------------------|--------|-----------|
| ERNEST WILLIAM HEY GROVES | 532    | 2         |
| GEORGE GRAY TURNER        | 426    | 3         |
| VINCENT WARREN LOW, C.B.  | 398    | 38        |
| VICTOR BONNEY             | 361    | 8         |
| FRANK LOTT, C.B.E.        | 306    | 27        |
|                           | 270    | 11        |
|                           | 264    | 10        |
|                           | 259    | 1         |
|                           | 222    | 5         |
| usc.                      | 181    | 18        |
|                           | 172    | 4         |

In all, 1,100 Fellows voted (including 184 Fellows resident out of the United Kingdom), 1,036 sending their ballot papers through the post and 4 voting in person. In addition, 2 voting papers were found to be invalid. Mr. Low becomes substitute Member of Council for Mr. Sherren until July, 1933, and Mr. Bonney becomes substitute Member of Council for Sir Charles Ballance until July, 1930.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the College held on July 2nd the following candidates, having passed the Final Qualifying Examinations under the conjoint scheme of the Irish Royal Colleges of Physicians and Surgeons, were duly admitted to the Licences in Medicine and Midwifery of the College:

Sybil Atkinson, Henrietta Carson, J. J. Fant, J. E. Harris, J. A. Hynes, J. Kennedy, W. Kingsberg, J. Molony, L. P. F. Nolan, W. O'Connor, J. O'Neill, T. S. Osborne, J. Owens, Catherine A. Quinn, C. Whitehead.

At the same meeting a letter was read from the secretary of the Committee of Management stating that P. Moran and N. K. Henderson had passed the examination for the Diploma in Psychological Medicine.

A letter was also read from the secretary of the Executive Council, Saorstát Éireann, forwarding a copy of a draft Order which has been prepared for the purpose of adapting the charters of the College in accordance with Section 1 of the Adaptation of Charters Act, 1926, and asking if the College has any observations to make thereon.

The College unanimously approved the draft Order.

## Medical News.

A CONGRESS of chemists has been arranged by the Society of Chemical Industry in connexion with its own forty-fifth annual meeting. The congress, which will be held in London, will open on Monday, July 19th, and continue until Friday, July 23rd. A joint meeting of the Biochemical Society with the London Section of the Society of Chemical Industry, to be held at the Hotel Great Central on Tuesday, July 20th, will be devoted to a discussion on hormones; it will be opened at 11 a.m. by Dr. H. H. Dale, F.R.S., with a paper on the experimental study and use of hormones. He will be followed by Dr. H. W. Dudley, who will deal with the chemistry of the pituitary gland and of insulin; by Mr. F. H. Carr, who will discuss the commercial production of hormones; by Dr. H. A. D. Jowett, who will speak on the history of adrenaline; by Professor G. Barger, F.R.S., whose subject will be recent progress in the chemistry of thyroxine; and by Dr. J. W. Trevan, who will explain the biological assay of hormones.

Nature states that at an extraordinary general assembly of the International Research Council on June 29th the Executive Committee agreed to omit from the statutes words which have limited membership to allies and neutrals. On the motion of the president of the Royal Society a resolution was unanimously adopted deciding to invite Germany, Austria, Hungary, and Bulgaria to join the International Research Council, and the unions attached to it.

DR. R. M. COURTAULD, a Cambridge medical graduate, has given an endowment to Pembroke College for the purpose of establishing a studentship in physics and cognate subjects. The student appointed will be called the "Stokes student," in memory of Sir George Gabriel Stokes, formerly Master of the College. No distinction of sex will be made in awarding the studentship, but if a man is appointed he will be required to become a member of the college. Preference will be given to graduates of the university. Candidates must be between the ages of 23 and 30, and must have shown capacity for research in mathematical or experimental physics, or in cognate subjects. The student will be expected to devote himself to research in Cambridge unless permitted for a limited time to conduct his researches elsewhere; he may give a course of lectures each term. The value of the studentship will be between £400 and £450 a year, and the tenure will be for three years, with possible renewal for a further five years.

FROM January 3rd to February 20th 2,359 fatal cases of plague occurred in the Dutch Indies.

THE annual general meeting of Fellows of the Royal Society of Medicine was held in the Barnes Hall, 1, Wimpole Street, on July 1st. The President, Sir StClair Thomson, in introducing the annual report of the Council, drew attention to some of the outstanding events of the session, more especially the important developments in regard to the library. Dr. R. H. Cole expressed the gratitude of the Society to Sir StClair Thomson for his gift of a presidential chain and badge of office, and a warm vote of thanks to the outgoing president for his generous services was carried on the proposal of Dr. Robert Hutchison and Mr. Walter Spencer. The president for the ensuing year, Sir James Berry, and the other officers were declared duly elected. The Council of the Society has awarded the William Gibson Research Scholarship to Miss Alice Bloomfield, who will hold it for two years.

THE North-East London Post-Graduate College is holding at the Prince of Wales's General Hospital, Tottenham, N.15, a special vacation course from July 19th to 31st. It will include as on previous occasions practical demonstrations of clinical and "side-room" methods each morning from 10.30 to 12.45, demonstration of groups of selected illustrative cases from 2 to 2.45 p.m., general hospital work, in-patient and out-patient clinics, operations, demonstrations in the special departments of the hospital, and at 4.30 p.m. each day a clinical lecture, the opening lecture of the first week being by Dr. T. Watts Eden on ante-natal care as it affects the child *in utero*, and that of the second week at 3 p.m. by Lieut.-Colonel L. W. Harrison on the diagnosis and treatment of syphilis, to be illustrated by cinematograph films. On the Saturday morning at 11 there will be demonstrations of cases illustrating the diagnosis and treatment of the infectious fevers, at the North-Eastern Fever Hospital, St. Ann's Road, N., and of typical cases of mental disease at the Colney Hatch Mental Hospital, New Southgate, N. Luncheon will be obtainable in the neighbourhood of the hospital, and tea will be provided in the hospital each day at 4 p.m. The fee for the course is 5 guineas, or 3 guineas for either week. The names of those wishing to attend should be sent (by Friday, July 16th, if possible) to the Dean of the College or to the Secretary of the Fellowship of Medicine, at 1, Wimpole Street, W.1.

A MEETING of the Biochemical Society will be held this day (Saturday) at Oxford beginning at 2.30 p.m. Two demonstrations will be given and a number of papers will be read.

THE Fellowship of Medicine has arranged a clinical demonstration in surgery by Mr. Rocyn Jones at the Royal National Orthopaedic Hospital, on July 12th at 2 p.m., and one in ophthalmology at the Royal Eye Hospital on July 14th at 3 p.m. by Mr. Griffith; both demonstrations are open to medical practitioners without fee. A late afternoon course will be held at the West End Hospital for Nervous Diseases from July 19th to August 12th. Practical courses in obstetrics and child welfare have been arranged at the City of London Maternity Hospital; the duration of each course is one week. Practical courses in anaesthetics can be arranged. From August 9th to 14th there will be an intensive course at the Brompton Hospital; an all-day course in diseases of children at the Queen's Hospital from August 16th to 28th; and an all-day course at Queen Mary's Hospital in medicine, surgery, and the specialties from August 23rd to September 4th. Copies of all syllabuses may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE annual dinner of past and present students of St. Mary's Hospital Medical School will be held at the Connaught Rooms, Great Queen Street, London, W.C., on Monday, October 4th, at 7.30 p.m.

A COMPLIMENTARY dinner was given to the president of the London and Counties Medical Protection Society, Sir John Rose Bradford, K.C.M.G., M.D., F.R.S., on June 23rd at the Grand Hotel to celebrate his recent election to the presidency of the Royal College of Physicians of London. Dr. C. M. Fegen, chairman of council, occupied the chair and was supported by the vice-presidents and members of council, including the legal officers of the society.

AT the general meeting of the People's League of Health, on July 5th, the Lord Mayor announced that the King and the Prince of Wales were subscribers to the £100,000 endowment fund which the league was endeavouring to obtain. Lord Burnham, speaking on the general work of the league, emphasized the importance of co-operation between the various nations in matters relating to health in order that higher standards of humanity might be secured. Professor Edgar Collis, Dr. A. F. Tredgold, and Professor W. E. Dixon dealt with the aims and objects of the league from the physiological, psychological, and public health aspects. Resolutions were passed in favour of the provision of periodical medical and dental examinations for insured persons, and advocating an inquiry by the Government into the influence of the dole on the national health and character.

IN our issue of June 12th we announced that the Manson medal of the Royal Society of Tropical Medicine and Hygiene had been awarded to Professor Ettore Marchiafava of Rome. The formal presentation was made at the meeting of the society on June 17th by its president, Dr. Andrew Balfour. The Italian Ambassador and Baron San Severino also spoke on this occasion.

EIGHT deaths from puerperal septicaemia having occurred during the first six months of this year among patients attended by nurses on the staff of the Kingston District Nursing Association, questions were asked in Parliament, as mentioned in our issues of June 19th (p. 1069) and July 3rd (p. 40). The Minister of Health has now written to the chairman of the Kingston Association expressing his concern and sympathy with the relatives and friends of those who died, and stating that the inquiry by one of the medical officers of the Ministry indicated the existence of grave laxity on the part of the superintendent in the administration of the nursing home and of the midwifery practice. The same nurse had access to infected and non-infected patients, and a nurse suffering from septic infection had remained on duty in spite of her manifest unfitness to continue in attendance on maternity patients. The Minister thinks there can be little doubt that this nurse acted as a carrier of virulent infection, and that both she and the superintendent cannot be exonerated from blame. He adds that he cannot escape the impression that the medical care in more than one case did not seem, so far as the evidence shows, to have been in accordance with the principles of sound midwifery practice. He expresses approval of the action taken by the Kingston Association in closing the maternity home temporarily and suspending the district midwifery practice, and he suggests that when maternity work is resumed the superintendent and the nurse concerned should be replaced by others, and that an entirely new midwifery staff should be appointed. The Minister refers to the long record of good and successful work by the association and is sure that its valuable public service will not be allowed to lapse. He suggests that it might be advisable for the committee to consider affiliating its association to the Surrey County Nursing Association.

THE eighth annual meeting of the Mental Hospitals Association will be held in the Council Chamber of the Guildhall, London, on Wednesday, July 14th, at 11 a.m.

THE thirteenth congress of French-speaking alienists and neurologists, which will be held in Geneva and Lausanne in the first week in August, will coincide with the centenary of Pinel's death, and will have as presidents one of his descendants (Dr. Semelaigne of Paris) and Professor Long of Geneva. The following subjects will be discussed; Schizophrenia, introduced by Professors Bleuler of Zürich and Claude of Paris; *Babinski's sign, its causes, mechanism, and significance*, introduced by Professor Claude; the treatment of mental diseases by work, introduced by Professor Ladame of Geneva and Dr. Demay of Clermont. The subscription for members of the congress will be 30 French francs.

A FURTHER series of tours has been arranged by the *Bruxelles-Médical* for the autumn. From August 31st to September 21st a cruise to the Canary Islands will include visits to Bilbao, Vigo, Oporto, Las Palmas, Almeria, or alternatively Casablanca and Tangiers and Marseilles; the charge to medical practitioners for the complete journey will be £26. Visits to the French ports are being organized during August and September lasting fifteen to eighteen days at the cost of 1,800 francs. Two Mediterranean cruises for university students will be organized in August and September, visiting Egypt, Palestine, Turkey, Greece, and Italy; the charge for the first cruise of twenty-six days will be 1,800 French francs, and for the second—lasting thirty days—2,100 francs. Further information may be obtained from the *Bruxelles-Médical*, at the Belgian office of the Compagnies Françaises de Navigation, 29, Boulevard Adolphe Max, Brussels.

THE thirty-sixth French Congress of Surgery will be held at the Paris Faculty of Medicine, under the presidency of Professor J. L. Faure, from October 4th to 9th, when the following subjects will be discussed: (1) Pathology of the semilunar cartilages, introduced by MM. Mouchet of Paris and Tavernier of Lyons; (2) Conservative operations in inflammatory diseases of the adnexa, introduced by MM. Gervais de Rouville of Montpellier and Mocquot of Paris; (3) Treatment of active gonococcal arthritis, introduced by MM. Michel of Nancy and Mondor of Paris.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are *MUSCUM 9361, 9362, 9363*, and *9364* (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### INCOME TAX.

#### Deduction for Cost of Professional Rooms.

"A. R." has for many years been allowed to deduct two-thirds of his rent and rates as incurred for professional purposes; the local inspector of taxes has now informed him that he will be allowed one-third only in future.

Two-thirds was the old maximum proportion. The test is what is reasonable in the circumstances of each case, and it has to be admitted that that is usually excessive in the case of a provincial town. If, for instance, "A. R.'s" combined rent and rates amount to £150 per annum, it is unlikely that £50 only

(or any amount near that figure) would reasonably cover the non-professional portions of the house and garden. But whether one-third is enough we cannot say. It may be worth while pointing out to the inspector that the garage is wholly (or almost wholly) used for professional purposes and that the ground floor, where presumably "A. R." has his waiting and consulting rooms, is always reckoned by valuers to be by far the most valuable portion of a house.

#### Private Use of Car.

"H. L." explains that (excluding holiday running, which is separately recorded) he uses his car privately to the probable extent of 300 miles a year, and that on that basis the inspector of taxes proposes to disallow his claim to expenses to the extent of from £20 to £50, according to the total amount expended in the year.

It must be admitted that any expense which "H. L." has incurred for non-professional purposes cannot properly be deducted in his income tax return, and that it is not uncommon for the taxing authorities to insist on the exclusion of such expenses. At the same time the amounts suggested seem excessive on the mileage basis quoted. (Perhaps "H. L." has not made it clear to the inspector that his holiday expenses have not appeared in his original claim?) There are some expenses (cost of garaging and licence, for instance) which are not increased by private use of a car, and we are of opinion that the whole of such expenses should be allowed.

## LETTERS, NOTES, ETC.

### DUPUYTREN'S CONTRACTION.

DR. T. M. ALLISON (Newcastle-on-Tyne) writes with reference to the annotation on "The machine and the man" (p. 839): I regard Dupuytren's contraction as a gouty fibrosis; I have never seen it except in a person who drinks beer, not necessarily to excess. The use of certain tools may irritate the hands, but the contraction, in my opinion, only occurs in gouty subjects.

### CALCIUM IN OVARIAN INSUFFICIENCY.

"OBSERVER," referring to the recommendation by Crainicianu of calcium in ovarian insufficiency (*Eptome*, June 26th, 1925, para. 652), asks what evidence there is of a deficiency of calcium in hypofunction of the ovaries; an excess of calcium might, he thinks, readily lessen the function of the ovaries, as well as that of the thyroid. Our correspondent adds: We know that the ovaries stimulate calcium metabolism, and also (as has been shown by Professor Dixon) the secretion of the pituitary body; but how calcium could stimulate the ovaries requires some explanation. In the treatment of osteomalacia the removal of the ovaries has long been practised. There is no use in introducing huge doses of calcium lactate into the digestive tract unless its absorption can be ensured, and it is known that only a small amount of calcium (fortunately) can be introduced into the system. If it were otherwise many patients would become like Lot's wife.

### HAFFKINE'S PROPHYLACTIC FLUID.

WITH reference to the proposed improvement of Haffkine's prophylactic fluid by using the clear filtrate and rejecting the sediment, Dr. S. MALLANNAH (Hyderabad, Deccan) writes: Up to the present it has been generally thought that the protection produced by Haffkine's fluid is due to the action of dead plague bacilli and their products, and hence it is directed that the bottles be well shaken before use, so that both dead bacteria and their products are used in inoculation. In 1900 I formed and published conclusions based on clinical and experimental observations to the effect that the filtrate of Haffkine's fluid, when free from sediment containing dead plague germs, was not only efficacious in producing immunity, but that it was better than the whole fluid, since it did not cause indurations at the site of injection (**BRITISH MEDICAL JOURNAL**, 1900, i, p. 1155). These indurations or lumps generally last for three or four months and are slowly absorbed. They contain sterile pus, as I have demonstrated. I have shown also that rabbits inoculated with whole Haffkine's fluid lose weight during the absorption of these indurations. Finding that the filtrate has a better protective power and does not produce hard lumps, my usual procedure in using Haffkine's fluid is as follows. The bottles, after being well shaken, are set aside for some days with the pointed ends directed upwards. After a few days the fluid becomes quite clear, and at the bottom there is an ash-coloured sediment, which consists of dead plague bacilli. I withdraw the clear supernatant fluid and use it for injections, rejecting the sediment. With this procedure I have obtained better results and less reactions without producing any induration. One great advantage in using the filtrate, or clear supernatant fluid, only, is that contamination can be easily detected, since it causes turbidity in the fluid; in such a case the bottle should be rejected.

### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 39, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 86.

## Victor Horsley Memorial Lecture

ON

## THE INSULATION OF THE NERVOUS SYSTEM.\*

BY

WILFRED TROTTER, M.S., F.R.C.S.,  
SURGEON, UNIVERSITY COLLEGE HOSPITAL.

WITHIN a few days it will be exactly ten years since Victor Horsley died. The circumstances of his death, however lamentable they may seem to us who lost him, were not, perhaps, very different from what he himself might have wished. He was at work in the direct service of his country, he was using his whole strength in the relief of suffering, while his mind and body kept unabated their astonishing and characteristic vigour. In commemorating this great man our attention is attracted to three separate aspects of his life. We think of him as a physiologist and as a surgical pioneer, and we think of the personality which lay behind and informed these and all the activities of his crowded years.

His work for science and for surgery has long been incorporated with the general body of knowledge and has its lasting place. For his personality there is no such lodgement, and those in whose memory it lives so vividly are already, after the passage of even ten years, a heavily reduced company. I therefore gratefully accept this chance to make my small record of a man who in my knowledge of men was unique in this—that he combined an inflexible belief in his own standards and a truly apostolic zeal in all public affairs, with a disposition that was in its essence boyish and simple and in every private relation easy and mild and kind.

## METHODS OF INVESTIGATION IN NEUROLOGY.

The pioneer work of Horsley in the surgery of the central nervous system has had and must continue to have important remote and secondary effects upon the development of neurology. Whenever a region of the body has been made accessible to surgery, a new insight into its pathology has resulted from the fresh experience that has been acquired of morbid processes in the living and especially of the earlier stages of disease. This has been abundantly shown in the case of the abdomen and in the case of the thorax. In that of the central nervous system it is perhaps as yet less obvious, but it is already unmistakable and will become increasingly so as experience accumulates.

While most of us would no doubt agree that important practical knowledge is to be acquired in this way, there are probably few who look to it with much hope for the discovery of principles of general scope and fundamental significance. As a possible source of any wide expansion of neurological theory it is just and natural to look to laboratory methods and the study of animals rather than to methods of the bedside and to the study of man himself in his reactions to injury and disease. In the familiar and not always philosophically made comparison between the experimental and clinical methods it is usually, however, overlooked that the latter has of necessity a virtue which is in some degree its special possession. The student whose material is man is drastically handicapped by the limited extent to which experiment is open to him. He must take his problems as he finds them, and deny himself the help of almost all the preliminary simplifications which are the essence of the laboratory worker's advantage. At the same time, however, the conditions of his work impose upon him a knowledge of his material at once so intimate and so wide as to constitute a situation probably unique in the whole field of science. When we consider the intensity of watchfulness which the quite ordinary practice of neural

surgery calls for and obtains it must be obvious that the behaviour of the human brain in the various circumstances of injury and disease is far better known than that of any other animal. Indeed, one of the characteristic difficulties of the clinician comes from this very abundance of the stuff of observation, and he is likely to be overwhelmed by its bulk and rendered inattentive by its familiarity, losing amongst details his sense for larger groupings, and amidst the everyday his eye for the significant. Nevertheless the history of science shows that one important source of general ideas has been just this very circumstance of a close intimacy with a large range of observed facts.

The familiarity with the behaviour of the central nervous system that has been possible since it has been accessible to surgical exploration and treatment is capable of reacting in an important way on our attitude to neurological theory.

## THE ABSTRACT METHOD IN NEUROLOGY.

There are few departments in biological science in which what we may call abstract methods of thought are more naturally and inevitably used than they are in neurology. By abstract methods I mean methods in which the single or grouped items of experience are for convenience of thought represented by abstracted summaries of themselves or symbols, which have a handiness for working on in the mind that the raw undigested facts cannot possess. The discovery of the uses of abstraction was an event of fundamental importance in the evolution of science, and in the early Greek natural philosophers we can see with what exultation was welcomed the extension it gave to the powers of the mind. Perfectly legitimate and indeed indispensable as the method is, it is obviously not applicable to all material of inquiry with equal ease and safety. With what certainty and precision the qualities of number, space, and motion allow of abstraction is seen in the noble achievements of mathematics, physics, and astronomy—achievements which, through their most recent extensions in atomic and in stellar physics, have finally established the overwhelming prestige of the method and its effective leadership in science.

When, however, we make living matter and living organisms the subject of study we find that though we can by no means dispense with the use of abstraction it is far less effective in application and has disadvantages which it does not seem to possess in the inorganic world. In biological inquiry an abstract conception, though professedly no more than a convenient summary of experience and constantly subject to the censorship of facts, is apt to acquire a quasi-vitality of its own through which it loses its immediate dependence on experience and comes to dominate instead of serving. The danger arises not so much from the extreme cases of conceptions which easily show as flagrantly inconsistent with facts, but from ideas primarily good and sound which have been endowed with a prestige that in their very nature they could not deserve. That an overvaluation of the abstract conception as an implement of research can deceive even the very elect could be shown by many eminent examples. The biological writings of Herbert Spencer are perhaps as good an instance as comes readily to mind, and it is easy to trace in them how this very weakness has led within a few years to their greatly diminished influence. To find so distinguished a man in a state of reprobation may well make humble people look anxiously to their own doctrines; and indeed which of us, for example, can ask himself without a qualm what is the *exact* meaning he attaches to the abstract conception of evolution which has dominated the biological world for half a century?

When we turn to neurology we find the currency and influence of abstract conceptions very great—as, for example, in the theory of aphasia, in Hughlings Jackson's interpretation of cerebral functions, in Monakow's doctrine of diaschisis, and so forth. All these are doubtless, in their essence and originally, good and valuable conceptions; it is another matter, however, how far their function as professed summaries of experience is kept distinct from their charm as mere intellectual patterns. It is thus peculiarly necessary for neurology to submit itself to the

\* The second Victor Horsley Memorial Lecture, delivered at the House of the British Medical Association on Friday, July 9th; Sir John Bland-Sutton, Bt., F.R.C.S., was in the chair.

discipline of frequent returns to the comparatively primitive and clumsy method of direct and concrete thinking. Such efforts should, I think, be guided by two principles. The first is the obvious one that a constant and docile reference to experience is indispensable. The second is perhaps less obvious and is less simple to state; it accepts the free use of hypothesis as essential to neurological progress, but it enjoins that in drawing up our necessarily more or less abstract conceptions of the nature and working of the nervous system we should incline to the use of ideas of a definitely biological type, and should as far as possible avoid concepts that in their very nature can have no direct resemblance to what actually happens in the body. In giving to our neurological ideas this concrete and realistic tone we shall always depend to a great extent on an intimate familiarity with the appearances and behaviour of the actual nervous tissues. The knowledge of this kind we possess to-day may well be regarded as having in great part grown out of Horsley's work.

The surgical neurologist is perhaps fortunately placed for considering the nervous system in an attitude of mind at once general and concrete; while he lacks the special knowledge of the anatomist, the physiologist, and the pathologist, he is also free from their special preoccupations; while the behaviour of the nervous tissues in injury and disease is a matter of familiar knowledge, it is prevented from becoming commonplace by the narrow margin of safety within which he works and the serious consequences that follow when it is exceeded. Thus is almost forced on him the development of views which, whatever they may lack in the way of abstruse detail, will at any rate always tend to be strictly realistic.

#### INJURIES TO THE LIMITING STRUCTURES OF THE NERVOUS SYSTEM.

In illustration of this general point of view I propose to call attention to a small group of facts which while they are of more or less common knowledge are perhaps more especially within the observation of the surgeon. They are concerned with the responses of the nervous system to certain injuries.

##### *Division of a Nerve.*

It is a very old observation that when a mixed peripheral nerve is cut its central end becomes swollen into a bulbous mass of dense fibrous tissue. It seems sometimes to be thought that this is only an occasional result of a nerve section and is especially to be looked for when persistent pain has followed the injury. This is, of course, not the fact. The bulbous end is the invariable and inevitable result of a nerve section to which it is the necessary and so to say physiological response. When we inquire into the exact nature of this so-called amputation neuroma we find that in immediate consequence of the section the nerve fibres ramify and grow out from the cut end so that there issues from this a veritable spray of fine naked axis cylinders. The result of this invasion is to call forth an energetic response from the adjacent non-neural tissue leading to the formation of a peculiarly dense fibrous material that resists the spread of the nerve fibrils and finally encloses them in an impenetrable capsule. Within this limiting substance the growth of axis cylinders continues, but since there is no exit it can result only in the formation of an intricate and aimlessly convoluted network.

##### *Breaches of the Spinal Theca.*

It occasionally happens, usually perhaps in connexion with the avulsion of a spinal nerve, that a subcutaneous laceration of the spinal dura occurs. More commonly the surgeon has an opportunity of studying the effect of breaches of the theca in cases where a laminectomy with incision of the membranes has to be followed by a second similar operation after some weeks or months. We find then that wherever the cerebro-spinal fluid has been able to escape into the tissues it has been everywhere walled off by a dense impervious membrane, so that, according to the extent to which the fluid has made its way, there will be a more or less complicated series of cyst-like spaces

communicating with the intrathecal cavity. It is the wall of these cystic extensions of the theca that is of interest, for it shows all the characters of the normal dura. It is of a dense, fibrous substance, its inner surface is smooth and glistening, and its outer surface, instead of merging with the surrounding tissues like a scar, is easily separable from them along a well marked line of cleavage.

##### *Regeneration of the Cerebral Dura.*

It is not uncommon for a second cerebral operation to be necessary in a case in which the dura mater has already been opened or removed. If the second operation is done after an interval of about six weeks or more it will be found that the gap, however large, that was left in the dura at the first operation has been closed by the formation of a new membrane having all the characters of normal dura as above described. Among such characters the most striking, and perhaps the most conclusive of the nature of the new membrane, is its differentiation from the overlying scalp, so that the latter can be stripped away from it with ease and without bleeding. It is interesting to note that at one time a great deal of surgical ingenuity was expended on evolving a plastic surgery of the dura, in which gaps were closed by the insertion of fascial grafts. Such grafts were always remarkably successful because a new dura would have formed quite naturally and equally well without them.

Here we have a group of three well defined facts established by countless observations and capable of confirmation at any time. They bring evidence from different parts of the nervous system disclosing even to superficial consideration a clear common tendency. The conclusion to which all point is that breaches of the normal coverings of the nervous tissues allowing contact between the latter and other tissues of the body, result of necessity in energetic local reactions. The obvious function of such reactive processes is to re-establish the normal discontinuity between neural and somatic tissues and to break the contact that has caused the disturbance.

We have met, then, with a mechanism of a definitely physiological type which may well prove to be concerned with the very nature of the nervous system. Our next inquiry will naturally be, What is the immediate agent of the reaction we are concerned with? In the case of the divided nerve it seems clear that the escaping naked axis cylinder is the actual irritant substance; in the case of the spinal theca it is evident that the cerebro-spinal fluid is the effective agent; in the case of the cerebral dura it is probable that in ordinary conditions with an intact arachnoid, fluid exuding through this is the excitant, though the contact of the brain itself is doubtless also effective. It is seen, then, that there is a common property possessed by naked nerve fibres, by cerebro-spinal fluid, and almost certainly by the brain substance itself, which enables these to set up in the somatic tissues an energetic reaction the tendency of which is to insulate the one from the other. There is evidence that the neural side of the contact, while effective as an irritant, does not contribute to the newly formed tissue which, whether in the form of the fibromatous material of the bulbous nerve or in that of the extemporized dura, is of purely non-neural origin though obviously a highly specialized material and no mere scar.

##### FUNCTIONAL EFFECTS OF BREACHES IN INSULATION.

When we see such well defined mechanisms for the sealing of breaches in neural insulation we naturally should expect to find such breaches to be of great functional importance and capable of causing serious disturbance in the tissues unnaturally brought into contact. There is in fact evidence that some effect on function is produced, but it is not to the mere prevention of this that we can look to explain the actual existence of these mechanisms themselves; that seems to depend, as we shall see, on some far more fundamental causation. The chief evidence of disturbed function is seen in the case of the divided nerve. Here there are symptoms suggesting persistent excitation of the cut end. These are always present from the first, but they vary greatly in intensity. The sensation of the presence of the limb after an amputation is universal, and it always lasts for several weeks. Not uncommonly it is

painful, and then it tends to be more persistent and may last for years. The facts suggest that the exposed nerve fibres of the stump are excited by contact with the tissues, and that in the bulbous end the stimulation effect gradually dies down until a state of equilibrium is established in which the new tissue sealing off the nerve end is practically as inert towards the nerve as is its normal sheath.

It is natural to suppose that after a wound of the brain which allowed a scar of non-neural origin to come into close contact with the brain substance a state of excitation might be set up. The frequency of traumatic epilepsy in cases of direct scarring of the brain is perhaps suggestive, but I know of no evidence that allows us to take the case beyond a mere suspicion.

On the somatic side of a breach of neural insulation there is no disturbance of function beyond the mere reaction already described. It is, indeed, characteristic of this that it is always and only strictly local. There is nothing in the way even of a diffuse or spreading fibrosis; the new tissue, whether it be an amputation neuroma or a new segment of dura and although it is of somatic origin, becomes sharply differentiated from the tissues it is derived from, and can be separated from them easily without cutting. We see, therefore, that although breaches of neural insulation are immediately dealt with by energetic, effective, and highly specialized mechanisms, the actual disturbances of function produced by such breaches do not seem to be very important.

#### INSULATORY ARRANGEMENTS IN THE NORMAL NERVOUS SYSTEM.

If the evidence I have cited bears the meaning I have given it and we can regard as of high importance to the body the maintenance of neural insulation, then we can look for confirmation in normal structure and expect to find dispositions in relation to the nervous system which are insulatory in function. From the nature of the reaction we have seen to be set up by breaches of insulation we may infer that the influence against which insulatory mechanisms are provided is chemical in kind, and this inference may serve as a guiding principle in the search.

#### *Insulation of the Peripheral Nerves.*

Beginning our survey with the peripheral nerves we may at once dismiss from consideration the medullary sheath, which, whatever its physical insulatory function may be, is clearly not in question as a chemical insulant, since non-medullated nerves lie as peacefully and as inert in the tissues as the medullated. The case is different, however, with the neurilemma. Here we have a sheath common to all nerves outside the central axis, and continuous without a break from spinal cord or brain to end-organ. The motor nerve fibre is clothed from within the central nervous system to the muscle fibre, where the neurilemma completes the sealing off of unnatural contacts by becoming continuous with the sarcolemma itself. The sensory fibres are similarly clothed throughout their length; at their peripheral termination they enter end-organs all of which throughout a great variety of structure show—with one suggestive exception—so marked an encapsulatory arrangement that one cannot but think that here the need for insulation must be especially vital. The one sensory nerve fibre which is known to terminate in an end-organ which is not of a strongly capsular type is the fibre that serves the sense of pain. This fibre ends in a free arborization in the tissue to which it is distributed, and this terminal part is uncovered by neurilemma. It cannot but strike us as significant, though I shall not take up the point further at the moment, that this anomaly of a sensory fibre making naked contact with the somatic tissues should be a character of the fibre concerned with pain, a form of sensibility that in itself is so profoundly anomalous.

The view that the neurilemma is the chemically insulating structure we are looking for is confirmed by the fact that within the central nervous system, where insulation is otherwise provided, it is defective or altogether absent. A point further suggestive of the importance of insulation in the

peripheral nerves is the evidence we have that there is an upward drainage along their trunks, so that the products of their metabolism are probably kept from contact with surrounding tissues and are conveyed into the central theca.

#### *Insulation of the Central Nervous System.*

When we turn to the central nervous system we find that the method of individual insulation no longer prevails, but that the whole mass of the central axis is protected as one unit. Plainly, of course, it is the meninges which are chiefly concerned. Of these we have already seen that the dura has so important a function that accidental defects in it are repaired with very remarkable rapidity and completeness. The *mechanically protective* function of the dura, which doubtless has its importance, can scarcely be regarded as explaining its peculiarly impervious texture, its double endothelial surface, and the marked line of cleavage that separates it even when newly formed from the surrounding tissues. All these, however, acquire meaning when they are regarded as evidence of its *chemically insulatory* capacity. Effective as the dura doubtless is in its way, it deals only with one relatively small part of the problem of insulation. If we are right in supposing that all neuro-somatic contacts are inadmissible and that the blood and blood vessels belong to the somatic side of the frontier, the nutrition of so large a bulk of nervous tissue as the central nervous system must involve dispositions altogether unique in the body, and we should expect, in regarding the circulatory mechanisms of the part from this point of view, to meet with features of a very special kind.

The cerebro-spinal fluid and its circulation, the existence and disposition of the multiple membranes of the brain, and the absence of a recognizable lymphatic system in the ordinary sense of the term, constitute a picture which is unique, and has admittedly defied thorough explanation. Let us consider it in relation to the avoidance of undue contact between neural and non-neural elements.

#### THE CEREBRO-SPINAL FLUID.

Let me briefly review the strange facts of the physiology of the cerebro-spinal fluid as they are now known. The cerebro-spinal fluid is an extremely dilute secretion profusely poured out by the choroid plexuses of the cerebral ventricles. It flows through the central cavities of the brain and issues therefrom through the roof of the fourth ventricle into the subarachnoid space. Through this so-called space, which has rather the structure of a cellular sponge-work, it courses partly into the spinal canal, but chiefly upwards and forwards over the brain, to escape into the venous circulation through the arachnoid villi that project into the various lateral extensions of the superior longitudinal sinus. As is well known, any obstruction to the flow in any part of this intricate course downwards within the brain and upwards outside of it inevitably leads to an accumulation of the fluid and to hydrocephalus. Such obstructions are easily produced and common.

The cerebro-spinal fluid with its circulation, whatever function it may be there to perform, shows itself, then, to constitute a weak spot in the cerebral organization that as it were invites pathological attack. That the cerebral apparatus should contain an arrangement in some ways so seriously disadvantageous, suggests that the mechanism must have some deep functional significance that is indispensable to the physiology of the body.

There is no lymphatic system in the ordinary sense in the brain or spinal cord, and no flow outwards through the cerebro-spinal envelopes of anything corresponding with lymph occurs anywhere. It seems clear that products of nervous metabolism find their way into the cerebro-spinal fluid in the subarachnoid space; there is, in fact, strong clinical evidence that this fluid has a definite toxicity for the rest of the body, for when it is liberated into the tissues high fever is apt to occur during the short period before absorption is arrested by the inevitable reaction in the tissues that produces encystment. It is thought that metabolic products reach the cerebro-spinal fluid along the so-called perivascular lymphatics. These remarkable structures are

tubular extensions of the subarachnoid space which accompany and enclose the vessels that penetrate the brain to their finest ramifications. The interpretation of their meaning has long been regarded as a great difficulty, but if we accept the view that somatic structures like the blood vessels cannot be admitted to direct contact with the nervous tissues it is natural to regard the perivascular lymphatics as mechanisms to insulate the blood vessels from this contact. It may be assumed from what we know of the nourishment of tissues in general that there is some kind of leakage from the cerebral tissues comparable with lymph as found everywhere else and presumably of a not dissimilar concentration. This fluid will find its way to the subarachnoid space, presumably by the perivascular channels. The disposal of such a material may well be regarded as an exacting task. It is impregnated with products of nerve metabolism and is an eminently "neural" fluid capable of producing energetic reactions in any somatic tissue it meets. Thus there can be no question of its entering the blood stream in the relatively high concentrations that are satisfactory for lymph, and Nature meets the case by providing for its being heavily diluted before it is allowed to join the somatic blood in the cranial sinuses.

The most characteristic feature of the cerebro-spinal fluid as it exudes from the choroid plexuses is its remarkably low solid content. It is by far the most watery secretion produced by the normal body, and one might almost say it is an attempt by Nature to secrete pure water. It contains a small amount of the diffusible substances of the blood, but practically nothing else. So strong is the tendency to keep the fluid watery that the choroid plexuses have a truly astonishing impenetrability to drugs and other foreign substances circulating in the blood. Even the bile pigments in cases of jaundice fail to find a passage. This fluid, practically amounting to nothing but water, is secreted in large quantities; on rare occasions I have had the experience of seeing as the result of accident what was perhaps a large fraction of the total secretion of cerebro-spinal fluid discharged on the surface. The amount of fluid escaping has been very large and the consequent inanition correspondingly profound. The normal function of this great flow of water we may suppose with some confidence to be to flush through the whole subarachnoid space and to dilute the products of cerebral metabolism to such a degree that the resulting fluid can be safely admitted to the general blood stream. This view gets some confirmation from the evidence we have that the fluid in the subarachnoid space has a larger solid content than the fluid in the ventricles.

It is interesting to reflect that the source of this mysterious secretion which has given so much difficulty to the chemical physiologist may turn out to be no more abstruse a thing than Nature's nearest approach in the animal body to a spring of plain water; if this should be so, it may also remind us of the small and amusing coincidence that one part at any rate of the tortuous channel through which the fluid runs—the *aqueduct of Sylvius*—has since the very early days of anatomy borne a singularly exact and appropriate name.

In our review of certain aspects of the nervous system we have found reason to regard as of fundamental importance the preservation of an impenetrable barrier between the whole of the nervous system and the rest of the body. This barrier we have seen to be made up of a number of highly special structures and mechanisms. Its function is on the whole to prevent contact between the neural and the non-neural, but is also in certain places to permit it. These places are only two: first, where the motor nerve end comes into contact with the muscle fibre, and secondly, where the naked arborization of the pain nerve meets the tissue in which it is distributed. The nervous system is thus kept apart from the body, as we may say, in order that when the two are permitted to meet the reaction shall be the more energetic. It is in fact, then, of the very essence of nervous tissue that it should be different from the other tissues, so that it can irritate and be irritated by them. This necessity for a certain "strangeness" of the nervous system may possibly throw some light on its curious embryology. The origin of the nervous system, as

an epiblastic tube originating on the surface of the body and then sinking into its substance, has been investigated chiefly from the morphological point of view, and great ingenuity and research have been expended on it. It may be worth suggesting, however, that the problem has also a functional side, and that the epiblastic origin of an organ that is ultimately to be deeply embedded in mesoblastic tissues possibly has the function of contributing its strangeness, and therefore its effectiveness, to the nervous system as a whole. This quasi-hostility between neural and somatic, between brain and body, is a suggestive and perhaps a disturbing thought, but we shall not attempt here to follow it out.

#### NEURAL INSULATION IN PATHOLOGY.

It is more convenient at the moment to consider certain pathological evidence that has some bearing on the conclusions we have already reached.

That the central nervous system differs from other organs in having a certain inaccessibility has long been recognized in connexion with syphilis. The difference between the strictly extraneural mesoblastic infection of the meningeal gumma on the one hand, and the intraneural parenchymatous infection of general paralysis on the other, shows that the frontier between the two regions is as sharply marked pathologically as it is physiologically. Moreover, the relative inefficacy of antisyphilitic treatment in the parenchymatous infection reminds us that the frontier is also impassable for many drugs.

The dura and arachnoid are in some sense intermediate tissues, for they show a certain tolerance for both neural and non-neural contacts, the arachnoid having slightly greater affinities for the former, and the dura perhaps for the latter. That they are, however, fundamentally non-neural in their behaviour, and probably also in their nature, is suggested strongly by their relations to certain tumours. The glioma is probably the one truly neural tumour that affects the central nervous system. Although it behaves within the brain as a malignant infiltrating growth, its spread is restrained by the neuro-somatic barrier, so that while in exceptional cases it may affect the meninges and skull by pressure atrophy it can never invade them or extend to the tissues of the body. On the other hand, the so-called "dural endothelioma," which is relatively so common as a growth involving arachnoid and dura, frequently shows the power to infiltrate the skull and overlying parts as a malignant neoplasm; but although it may press deeply into the brain it never invades it, being restrained as effectively in the one direction as is the neural glioma in the other. The behaviour of these two tumours has long been familiar, but seems always to have been accepted as very much a matter of course. It is perhaps more reasonable to regard it as one of the most significant anomalies in the whole of pathology.

Our final pathological illustration takes us back to the peripheral nerve. We have already seen that this is the only part of the nervous system where a breach of insulation produces immediate and definite disturbance of function. The neurilemma seems fortunately, however, to be an exceedingly effective barrier between neural and somatic tissues. There is clinical evidence that a relatively slight subcutaneous injury can lead to the formation of a neuro-fibroma presumably through damage to the neurilemma; but this is a rare event of little practical importance, and failing gross injury the insulatory mechanism is wholly satisfactory. That this is the result of effective restraint rather than inertia on the side of the nervous system is perhaps shown by that fortunately rare complaint multiple neuro-fibromatosis or Recklinghausen's disease. In this condition it has been shown that every fibromatous formation, localized or diffuse, contains nerve fibrils which presumably by their irritant qualities, have given rise to the fibrosis, much as might a foreign body or a micro-organism of highly attenuated virulence. It seems clear that it is the presence on a large scale of nerve fibrils outside their normal insulating sheath which is the proximate cause of the morbid state. It may be doubted whether the neural leakage is a primary manifestation or is due to an essential weakness or collapse of the insulating

function of the neurilemma. Whether the failure of this sheath is primary or secondary, absolute or relative, no one who has seen a severe case of the disease can doubt that any general collapse of the peripheral insulatory mechanism makes the life of its unfortunate subject almost insupportable.

#### INSULATION AND THE PHYSIOLOGY OF PAIN.

I have already called attention to the remarkable fact that there is one kind of sensory fibre which ends in a free arborization in naked contact with the tissues. Our last task in dealing with the insulation of the nervous system is to examine a little more in detail the striking anomaly that in their end-organs the pain fibres make this unique exception to the rule that sensory fibres are insulated up to and including their end-organs.

This anatomical uniqueness of the pain fibre in its end-organ is matched by the uniqueness of the physiological characters of pain sensibility, and it is very natural that we should desire to correlate these two anomalies. Pain sensibility is remarkable in three respects: first, in the quality of the sensation itself; secondly, in its threshold of sensitiveness; and thirdly, in the nature of its appropriate stimuli. (a) The sensation of pain is peculiar in that it has a sudden and as it were explosive way of bursting into consciousness, in that it calls urgently and often irresistibly for some kind of motor response, and in that it is in its very nature distracting so as to be incompatible with quiet contemplation or steady judgement. (b) The threshold for pain stimuli is remarkably high, so that in comparison with other forms of common sensibility the stimulus has to be relatively energetic to call forth the characteristic sensation. (c) The stimuli that call forth pain sensations are remarkable for being very miscellaneous. In every other kind of sensibility but pain, the normal response is to a single well defined physical change—pressure is evoked by weight, touch by movement, cold by loss of heat, warmth by access of heat. The ordinary stimulants of pain, on the other hand, such as pressure, pin-pricks, cold, heat, and the electric current, make up a thoroughly odd class, the members of which show no common character. They are all capable of producing the characteristic sensation before, and usually long before, an intensity of stimulation is reached that can be shown to be harmful. That many of the stimuli would be harmful in greater intensities can scarcely, therefore, be regarded as forming a common physical basis, but must rather be explained as merely a consequence of the normally high threshold.

When we consider these peculiarities we can hardly regard them as those of a highly differentiated mechanism, but rather as those of one relatively crude. All sensibility may well have been of this kind in organisms to which the distracting explosive qualities of the sensation would be no detriment. If we look upon the peculiarities of pain as an evidence of crudity rather than of differentiation it is relatively easy to correlate them with the uninsulated end-organ of the pain fibre, which we must regard as less differentiated and cruder than the complex end-organs of the other fibres. Pain sensibility would thus owe its special character to being the function of a nerve fibre of a peculiar kind, which while relatively insensitive responds in an exaggerated way when its threshold is reached. Presumably these characters are to be associated with the uninsulated end-organ, and we may suspect that it is this lack of insulation which gives to the fibre its characteristic features of blunt sensitivity and emphatic response.

We possess a possible source of further light on this problem in the phenomena that accompany the recovery of function in sensory nerves after division and immediate suture. It is well known that this process, as observed under experimental conditions in the human subject by at least three independent groups of investigators, is accompanied by remarkable modifications in all forms of sensibility. It is impossible to refer to these modifications in detail, but it gives them in a broadly approximate way—and I speak from actual personal experience of them—to say that they are generally in the direction of the peculiarities shown by normal pain; in other words, the modified sensations compared with the normal are more explosive and more urgent, they have a higher threshold,

and they call for some kind of motor response. The explanation of these and the other modifications that are to be observed during recovery of sensory nerves has differed with different investigators. It is far too much a matter of detail to discuss these differing hypotheses here, but there is one criticism to be offered of some that is relevant to the general attitude we have tried to support. This criticism is that there has been a tendency to approach the problem in too abstract a way. It has been assumed that the question is one of the mere return of functions that are present in the normal and in the form in which they are then present—modifications in the character of sensation being ascribed to such factors as the order of return and the rate of return of different functions, and the modification in character of one form of sensibility to the presence or absence of another. This is to assume that the processes and incidents of regeneration itself have nothing to say to the problem; and that the struggle between the advancing nerve fibres and the reaction they arouse from the line of suture onwards can be ignored. To take it for granted that the naked growing fibres can pass through this difficult and prolonged ordeal without any alteration in their function, and to limit the problem in this way to strictly and exclusively neural factors, seems to me a method less concrete and practical than the case demands.

An alternative hypothesis, which is at any rate more comprehensive and more simple, can, however, be put forward. The general tendency of all forms of sensation yielded by a regenerating nerve to develop a certain resemblance to pain reminds us that regenerating fibres resemble pain fibres in a lack of complete insulation. It is probable, therefore, that imperfect insulation tends to render all fibres less sensitive than normal, but more apt when effectually stimulated to respond in an exaggerated explosive way. With the advance of regeneration the fibres serving touch, heat, and cold, become once more connected with end-organs, and then their insulation, by the junction of the neurilemma with the capsule of the end-organ, can be completed. The completely insulated fibre, having lost its temporary resemblance to the pain fibre, becomes once more sensitive to the finer stimuli and ceases to yield exaggerated responses.

The process of regeneration thus seems capable of causing a regression of function in all kinds of nerve fibres to a cruder type that in the normal is represented only by pain. This regression occurs because during regeneration insulation must necessarily be defective. According to this hypothesis normal pain and the sensibility of regenerating nerves give us an insight into the ancestry of common sensation. Primitive sensibility of all kinds we may suppose to have been like pain in us; it had a relatively high threshold, but it was effective because its sensations were urgent and explosive and, of course (also like pain in us), were exactly localized. Among such sensations fine discrimination was plainly impossible. With the development of the completely insulated nerve and end-organ the fibres thus equipped became capable of yielding sensation to finer and to specialized stimuli, and of a quality no longer explosive but able to be submitted to discrimination; at the same time the large number of pain nerves remained in their primitive state to warn the body of strong stimuli by urgent sensations among which there was no power and no need for discrimination because their function was to excite immediate response.

The great and manifest difference between the vertebrate and the invertebrate nervous systems is that the former is centralized and the latter is scattered throughout the body. The facts I have quoted and the inferences I have drawn suggest the hypothesis that, side by side with centralization and rendering it possible, insulation also must have proceeded. Insulation on the one hand must have been made increasingly necessary by the growing differentiation of neural from somatic tissues, and on the other hand must have helped to sharpen this very difference. It is not, therefore, surprising that a function so fundamental is not only recognizable in the structure and behaviour of the normal nervous system, but is also evidently at work in morbid processes and constitutes at once a help and a limitation to the work of the surgeon.

SPIROCHAETOSIS ICTERHAEMORRHAGICA  
IN NORFOLK.

BY

F. W. BURTON-FANNING, M.D.CANTAB., F.R.C.P.,

AND

A. J. CLEVELAND, M.D.LOND., F.R.C.P.,

PHYSICIANS TO THE NORFOLK AND NORWICH HOSPITAL.

DURING the last fifteen months we have seen four cases in Norfolk presenting the clinical features of spirochaetosis icterohaemorrhagica. Though the actual presence of the spirochaete was only proved in one, the symptoms and course of the disease were so similar and distinctive in all that we think we may assume the identity of their affection. The organism is acknowledged to be elusive, and we had no opportunity for animal inoculation. A closely studied series of eighteen cases in East Lothian has been described by G. L. Gulland and G. Buchanan,<sup>1</sup> but in England we find the record of only one case, by Dr. Philip Manson-Bahr.<sup>2</sup>

The cardinal symptoms of the disease are so few and so constant as manifested by our patients that a brief account of each will be given.

## CASE I.

A man living in the outskirts of North Walsham, who had retired and occupied himself in his garden, was in good health until December 9th, 1924. On that day he felt exhausted and unable to eat. For the next few days he remained in bed on account of this sense of prostration.

On December 13th he was seen by Dr. J. Shephard and later by Dr. D. Hart and one of us. The temperature was 101°, the pulse was 80, and the tongue was dry. On the following day jaundice was perceptible; the temperature was 99° and pulse 70.

On December 15th the temperature was 97.6° and pulse 60. But the jaundice had increased and the tongue was more dry.

On December 18th no urine was passed; the excretion had been diminishing previously. Haematemesis recurred every few hours.

On December 19th the condition was obviously grave; no urine was passed and haematemesis persisted. The temperature was 97, pulse 60, and the blood pressure 120.

On December 20th death took place somewhat suddenly. There had been suppression of urine for three days and melaena occurred. The liver and spleen had never been palpable.

## CASE II.

A tramp, aged 26, was admitted to the Norwich Poor Law Infirmary on May 3rd, 1925. He had been taken suddenly ill four days previously with prostration, headache, and dizziness.

On admission he was jaundiced, with epigastric tenderness, vomiting, and slight fever. The urine contained albumin and bile, but leucin and tyrosin were not present.

On May 6th jaundice was more marked, the tongue was dry, and he was drowsy. On May 10th there was epistaxis, and on May 13th he gradually sank and died.

Widal's reaction for the typhoid group was negative. No spirochaetes or other organisms were found in the urine, but the examination was not made of freshly passed urine. Blood drawn from the liver after death showed no spirochaetes.

## CASE III.

A farmer, aged 57, living in an isolated house a few miles from Fakenham, whose previous health had been good, was taken ill with general pains and chilliness on December 16th, 1925.

On December 17th he was seen by Dr. E. W. Palin, who found a temperature of 102°, pulse 100, and tenderness in the upper abdomen. During the next three days there was no marked change.

On December 21st no urine had been passed, and the bladder was found to contain only one drachm, which was free from albumin. The temperature fell to 98°, pulse 80. The next day slight jaundice appeared and there was frequent vomiting, the contents becoming coffee-ground.

On December 23rd the jaundice had deepened and there were haematemesis and melaena. On December 24th there was also free epistaxis. After three days' suppression some non-albuminous urine was passed.

During the next few days the urine was excreted, but the jaundice deepened and haemorrhage from the stomach, bowel, and nose persisted.

He died on December 27th. After his death his wife remembered that on December 10th he had been scratched or bitten on the face by a rat. No mark, however, was left.

## CASE IV.

A fowl-dealer, aged 53, from Hindolvestone, was sent to the Norfolk and Norwich Hospital by Dr. G. S. Keeling of Attleborough on January 23rd, 1926.

On January 14th there had been sudden onset of illness with general pains and rise of temperature, though an exact record

was not kept. On January 18th there was epigastric pain, relieved by vomiting, and hiccup. On January 19th jaundice was noticed; the liver and spleen were not enlarged.

On January 23rd the temperature was 97°, with pulse 92. The urine contained albumin and much blood. There were petechial haemorrhages about the skin. On January 26th profuse epistaxis occurred.

On February 2nd spirochaetes were found in the urine. From February 3rd to 18th the evening temperature was 99.4° to 100°, but gradual improvement was taking place, and on February 25th he was discharged convalescent.

In their important account of the disease Dawson, Hume, and Bedson<sup>3</sup> give as noteworthy features of spirochaetosis icterohaemorrhagica the following:

"A sudden onset with gastro-intestinal symptoms and high fever, the marked prostration, the occurrence of melaena and haemoptysis, the presence of haemorrhagic herpes, the appearance of jaundice on the fifth day, the fall of temperature at the end of eleven days, and the finding of typical spirochaetes in the urine."

Our four cases conformed closely to the above description in most particulars, but not in all. Our patients were attacked suddenly and prostration was extreme. With remarkable punctuality jaundice appeared on the fifth or sixth day. Haemorrhage from various parts occurred later with remission of fever. Herpes was absent in our cases. Renal symptoms were much more prominent. In two cases there was suppression of urine, though in one of these the excretion was re-established before death. Dawson, Hume, and Bedson refer to the fact that French authors "lay considerable stress on the evidences of renal insufficiency."

This suppression of urine obviously contributed largely to the fatal termination, and moreover prevented the confirmation of the diagnosis by the detection of spirochaetes in the urine. In our other cases there was albuminuria and in one of these there was haematuria. In Case iv the patient's general condition was very different from that of the others; he was never very ill, and haematuria was the chief renal affection.

The greatest contrast was in the gravity of the disease as we met it, for whereas Dawson, Hume, and Bedson estimate the mortality as from 4 to 5 per cent. amongst their cases seen in France during the war, of our four cases three died. There has been a remarkable disparity of mortality figures amongst foreign observers. We did not have the opportunity of using the antispirechaetal serum prepared for the Medical Research Council.

Dr. David S. Brough, assistant pathologist to the Norfolk and Norwich Hospital, kindly supplies us with the following information with regard to Case iv.

February 2nd.—A catheter specimen of urine was found by dark-ground illumination to contain spirochaetes in centrifuged deposit. They were numerous and as many as eight or ten could be distinctly seen in one field. Their spirals were more open and less regular than those of *S. pallida*, and their movement was slow and aimless. Some of the spirochaetes showed a certain amount of hooking of their ends. Spirochaetes continued to be found on each of the three following days, but at the end of five days had disappeared. Observations were made to ascertain the length of time during which spirochaetes could be recognized in the urine after its passage. It was found that at the end of twenty-four hours the spirochaetes were becoming granular and somewhat blurred, and after seventy-four hours were no longer to be recognized. Spirochaetes were not found in the blood.

Van den Bergh's Test.—Serum: (1) Biphase reaction; (2) faint indirect action; (3) no direct action.

Blood Count.—Red blood cells 3,500,000 per c.mm., white blood cells 14,600, haemoglobin 42 per cent., colour index 0.6. Differential count: polymorphs 78 per cent., lymphocytes 16 per cent., mast cells 3 per cent., mononuclears 3 per cent.

To verify our idea that this disease is rarely recognized as a cause of death in England we applied to the Registrar-General, who informed us that in the four years 1922 to 1925 there had been seven deaths in England classified as spirochaetosis icterohaemorrhagica in addition to our own cases.

There was no possible connexion between our four patients. They were all country dwellers, but none had been working in particularly damp places, nor was it clear that their areas were especially infested by rats, the recognized carriers of this disease.

# THE THYROID AND MANGANESE TREATMENT IN ACUTE PNEUMONIA.

BY

HERBERT W. NOTT, M.R.C.S., L.R.C.P.,  
LITTLE SUTTON, BIRKENHEAD.

Two papers on the thyroid and manganese treatment were published in the *BRITISH MEDICAL JOURNAL* last year. The introductory one (March 7th, p. 443) reported a series of cases, presumably of toxic origin, which had shown improvement enough to suggest that the method explained therein might prove useful.

The second (December 26th, p. 1209) was chiefly concerned in describing its influence in the treatment of abnormal blood pressures. An early verdict was asked for on this subject; and it is more than favourable, inasmuch as others have reported that the thyroid and manganese cachets are often successful in lowering high tension. This was not known when the paper was published, and these reports have come from as far as Central Africa.

Both papers were founded on facts observed by others besides myself, and so far no one has controverted them. On the other hand, confirmatory evidence is accumulating and an extension of the treatment has been suggested to other diseases. The present paper is to show the unusual effects which have been obtained when using it in the treatment of acute pneumonia.

What I have to say will be told in narrative form, and, as far as possible, free from details, because no one yet knows why potassium permanganate, held in aqueous solution and injected into the rectum, should give such good results. Besides which, it is undesirable to try the patience of readers with debatable points of a treatment for pneumonia so definite, so practical, and so obviously successful. The explanation will have to be thrashed out in laboratories and hospitals in this and other countries where team work is available.

How has it become possible to state categorically, and with no fear of contradiction, that ordinary pneumonia, unaccompanied by intercurrent affections, or occurring at too advanced an age, is one of the easiest diseases to arrest and cure? Mainly by the cordial co-operation and work of five doctors and two ladies—Drs. Kerr, Farr, and Pennington of Ellesmere Port, Dr. Hanratty my assistant, and myself; helped by the able services of Miss Jeans, matron of the Whitby Cottage Hospital, Ellesmere Port, and her assistant, Miss Barret. Had it not been for the untiring zeal of these two ladies much of what follows could not have been written until months had elapsed. By the courtesy of this group of observers I have been allowed to see some of their cases whilst under treatment, and I have before me notes, histories, and many of their temperature charts which, with our own, together with one from Dr. Grace of Chester, and another from Dr. Pirrie of Maldon, Essex, comprise forty cases.

I will not weary my readers by taking these cases seriatim, or by attempting to classify them, this being unnecessary when all of us have been using a single agent which has controlled every case of undoubted pneumonia treated with it from the age of 6 months to 71 years. Half of them were above the age of 18 and half below; the majority were cases of lobar pneumonia, and two deaths occurred—one a lady aged 60, and the other a man aged 71, both of whom died of intercurrent diseases, seven days after a lysis had been brought about in the first case and two days after a crisis had been induced in the latter. (See Dr. Grace's and Dr. Pirrie's abbreviated reports at the end of this paper.)

It was in March, 1924, that the first case of acute pneumonia was treated by this method.

A youth, aged 16½ years, received half a pint of the standard solution twice daily, beginning on the fourth day of the disease. His was a moderately severe case, with extensive involvement of the left lung. His temperature had reached 103.2°, with all the usual symptoms of distress and a moderate amount of rusty and adhesive sputum. Soon after the first injection had been given and retained he said he felt more comfortable, and could cough up the expectoration more readily. A few hours after the second injection his temperature dropped to 101.2°, and the rusty sputum

suddenly disappeared, never to return. His cough lessened rapidly, the expectoration became frothy and white, and still less difficult to get rid of. Greater relief followed the third injection, and thirty-six hours after beginning the treatment his temperature fell to normal. He was also given a thyroid tablet 1½ grain (dry 1/10 grain) twice daily, and this dose was continued for two weeks, but the injections were stopped on the eighth day. Convalescence was rapid and less exhaustion was observed than is usually seen after pneumonia.

The next case was that of a girl aged 12½ years, suffering from double pneumonia. She was the first to come into the hands of Miss Jeans and Miss Barret. She was treated in a similar way, beginning on the fourth day. Quick relief was experienced, but the temperature did not reach normal until the end of three days. Here again there was less exhaustion than is usual after an illness of such severity.

The third case was a man, aged 24, who had a small localized patch of pneumonia at the base of the left lung; he was sent to the same hospital, where he received two injections on the second day of the disease, three-quarters of a pint of the standard solution being given on each occasion. On the morning of the third day his temperature was 103.2°, but seven hours after the third injection it fell by crisis to normal, and remained normal. He wanted to get up the next day, declaring he had only had a chill and that it was absurd to say he had been suffering from pneumonia. But being assured that there were still signs of pneumonia in his lung he consented to stay in bed ten days, though all crepitations had gone by the third day after the crisis. Treatment was continued for a week.

These three cases suggested that potassium permanganate might have a true specific action on the organisms of pneumonia, so Drs. Kerr and Farr used it in a child aged 4 years in the last stages of pneumococcal meningitis, who was occupying a bed in the Whitby Cottage Hospital. This case was reported in my paper of March 7th, where it was described how the child did well and walked out of the hospital some three months after commencing treatment.

These two doctors, being now thoroughly interested in the subject, sent in quick succession four children suffering from bronchopneumonia, whose ages ranged from 6 months to 6 years. All did well, the disease aborting in two of them within thirty-six hours; and as at this time better results were being seen in the treatment of pneumococcal arthritis by giving three daily injections, more frequent injections became the custom at the hospital, and in private, when treating acute pneumonia. Somewhat later we found that by doubling the strength of the solution even better results were obtained (Figs. 1, 2, 4).

In the meanwhile Dr. Pennington had had good results in the toxæmias of pregnancy, and began using the method in pneumonia.

Recently he treated a man aged 50, a very desperate case, where the pneumonia was accompanied by alcoholic delirium and high fever. Besides Dr. Pennington, Dr. Farr and Dr. Hanratty saw him soon after admission, and all of them thought he was too hopelessly moribund to respond to the treatment. Yet he lived, and went out for walking exercise in the garden three and a half weeks later. He received injections, on an average, every four hours from the time of admission, and his temperature fell from 103° to 101° in ten hours. He was much less delirious, with fitful consciousness, in thirty-six hours. Twenty-four hours later he was completely conscious, with an almost normal temperature, and he began to grumble about the small quantity of food he was being allowed (Fig. 3).

A severe case of septic pneumonia, confirmed by bacteriological examination, has lately been treated.

A youth, aged 17 years, was carefully attended to by two nurses and treated on the principles described below. He was steered through a dangerous illness without undue anxiety to those in attendance. Dr. Murray Cairns of Liverpool saw this youth in consultation, and agreed with the method we were using, saying he had seen a case of streptococcal invasion of the lungs do well with it. No complications occurred in this case, and the patient was out of bed at the end of the third week. Dr. W. H. Grace (honorary pathologist, Chester Royal Infirmary) reported: "This sputum contained many streptococcal chains in the direct films and the cultures gave abundant growths of a *Streptococcus longus*. I considered this a very severe streptococcal pneumonia." (See Fig. 5.)

## THE TECHNIQUE.

When this treatment is used for pneumonia aperients are avoided as far as possible for fear of driving intestinal toxins into the circulatory system. The bowels are gradually unloaded by the permanganate injections, or small doses of calomel are given when evacuation is not as complete as it should be. The solution used is made by adding two grains of pure potassium permanganate to one and a half pints of water, which should be comfortably hot; from three ounces to half a pint are used on each occasion,

according to the age of the patient. The fluid should be administered very slowly by means of a funnel and small tube, or by a Higginson's syringe, and the injections repeated from two and a half to four hours during the first

appetite quickly returns, and this has to be anticipated and met by a more substantial diet than is the usual custom.

Too few cases, as yet, have been treated to say anything definite as regards the value of administering thyroid

FIG. 1.—Dr. Kerr's case: Bronchopneumonia; child aged 6.

FIG. 2.—Dr. Farr's case: Bronchopneumonia; child aged 5.

twenty-four to thirty-six hours. The length of the interval between the injections depends upon what day of the disease the case comes under treatment, much in the same way as the dosage and frequency of the subcutaneous injections of serum are judged in the treatment of diphtheria. In ordinary cases, if the treatment is begun on the first or second day of the disease, intervals of three or four hours can be allowed; but when beginning on the fourth or fifth day, especially when the symptoms are severe, the intervals may be reduced to two and a half or even two hours. One must be guided also by the quantities the patient is able to retain on each occasion, shorter intervals being necessary when the fluid is quickly returned. Once the temperature reaches normal the injections are reduced to two a day for three days, and once a day for three more days, when they can be discontinued; or they can be replaced to the advantage of some by giving the combined thyroid and manganese cachets for a week or so. But in infants and younger children the injections should be continued twice daily for at least ten days after the temperature has reached normal, as there is a tendency to recurrence if they are given up too early.

FIG. 3.—Dr. Pennington's case: Alcoholic pneumonia; male aged 50.

substance during the acute stage of the disease. Lately we have all come to look upon potassium permanganate as being specific in its effect, and most of us have not given thyroid even during convalescence. This is a matter for individual judgement and experience.

Those who, like myself, have seen the results of combining the two drugs in cachet form in treating toxic diseases will not hesitate to use it for a while during convalescence.

If it may be conceded that thyroid efficiency is reduced by the suffocating effects of all toxæmias, whether acute or chronic, then the body should derive benefit from thyroid feeding until the gland has regained its power.

#### EFFECTS OF THE TREATMENT.

The changes seen in the clinical picture when these permanganate injections are given are very rapid indeed. After the first or second injection the character of the cough alters from a harsh hawking bark to an easier and softer sound; the respirations become deeper and a little slower, with reduction of pleuritic pain in consequence. After the second or third injection the sticky expectoration becomes much looser and more easily raised. The grey or dusky type of cyanosis disappears in eighteen to thirty

FIG. 4.—Dr. Hanratty's case: Bronchopneumonia; child aged 5.

FIG. 5.—Septic pneumonia; youth aged 17.

A considerable quantity of mucus is seen in the stools, and the sooner it appears the more rapid is the improvement in the patient's condition. When ordinary uncomplicated pneumonia comes early under this treatment nothing more is ordered than a mild expectorant and poultices. Most cases have not needed hypnotics, but cardiac tonics and stimulants may be required, especially in septic cases. Owing to the rapid removal of toxæmia

hours, being often replaced by a rosy complexion in children, whilst in adults the pneumonia facies gives way to an expression of ease. Sleeplessness, if it has been a predominant symptom, ceases. After the very first injection a child with advanced bronchopneumonia will fall soundly asleep, and can be kept sleeping by repeatedly giving small injections. Reduction of active and noisy delirium is noticed after a few injections; the patient

quietens and is more readily controlled after three or four doses have been well retained. But the most dramatic change of all is the sudden ceasing of the coloured sputum. It is not uncommon to see a bright red sputum in the morning and to find white frothy expectoration in the evening of the same day.

Sometimes there is a little free haemorrhage for an hour or so just before this change takes place, and as this may alarm parents or attendants they should be warned that it may occur. An hour or two later the sputum may be milky white. The pulse and respirations settle down according to the course of the temperature, which itself may rise a degree or so before the crisis or lysis sets in. Indications point to mixed infections being rather less responsive, though a sufficient number of bacteriological examinations have not been made to settle the point. Crisis is not infrequent, but descent is by lysis in most cases, taking on an average from two to three and a half days from the commencement of treatment.

A few practical points must be mentioned in connexion with this treatment, whether it is being used for pneumonia or other toxic complaints, which if not carefully attended to may tend against success. In the first place, it is always advisable that the medical attendant be present when the first injection is given, for many mistakes may be made and valuable time lost; besides which it is reassuring to the patient to know that the treatment is being conducted properly. Nurses have been found giving vaginal injections when rectal ones have been ordered; some are too hasty or clumsy in using the syringe, or funnel and tube, and may irritate the patient; whilst others are to be found who frankly express an opinion that they have "no faith in the blue injections," and the fluid is thrown away accordingly. A temperature chart will sometimes clearly disclose mismanagement of this kind, and suspicions raised thereby have been followed by confessions.

A word must be said also as to the awkward situations which naturally occur when a child, who was looking deadly ill with bronchopneumonia three or four days before, is seen half-sitting up reading a book or playing with his toys as unconcernedly as though he had just recovered from an ordinary cold; and when this is accompanied with a ravenous appetite doubting parents may think the diagnosis has been at fault. In some cases it may be better to have confirmation at the outset, in the interests of the child, for, as has been said already, too early cessation of treatment may allow of recurrence. It is disconcerting, too, to find an adult in his fourth or fifth day of the disease, and whose temperature was 103.3° a few hours previously, now with a falling temperature, calmly smiling, and wiping a little blood from his lips, hardly more inconvenienced than if he had been just relieved of a painful tooth under a local anaesthetic. But this tame and unexciting ending is not what the public imagines the crisis of pneumonia to be, and the diagnosis may again be called in question. So what are we to say? Difficult, no doubt; but cannot we reply with a little more faith than of yore, "Perhaps this manganese has raised the patient's power of resistance to pneumonia"? Nor need it prevent our hoping that some day we shall be able to state this as a proven fact.

As the introductory paper referred to above begins by stating that the idea of this treatment originated in the study of Colonel R. McCarrison's works, so this contribution may end by saying that the quelling of the dangers and horrors of pneumonia, with the reduction in its death rate that will follow, has come in the first place from his brilliant book *Studies in Deficiency Diseases*.

Reports from DR. GRACE and DR. PIRRIE.

This man, aged 71, was admitted to the Royal Infirmary, Chester, in a semi-conscious condition on the sixth day of the disease. He was a case one would have expected to lapse into coma. But on receiving two injections of the standard solution of potassium permanganate his temperature dropped by crisis to normal, and he regained consciousness. He died two days later from heart failure, with myocardial degeneration.

W. H. GRACE, M.R.C.P.

This lady, aged 60, was a semi-invalid, and had been suffering from pyelitis and cystitis for some time, which flared up during her attack of pneumonia. Rectal injections of potassium permanganate

were given every four hours in her case, beginning on the third day of the disease; twenty-four hours later the temperature came down by a quick lysis from 103° to subnormal, taking three days to do so. Concurrently her pulse improved, and the respiration rate never exceeded 26; it was usually 22 to 24. She died seven days later from exhaustion caused by the pyelitis and cystitis. I have never seen a true pneumonia with such a remarkable absence of distress and toxæmia.

MASTOIDITIS AND ITS COMPLICATIONS.

BY

W. MAXWELL MUNBY, M.B., Ch.M., F.R.C.S.,

HONORARY AURAL SURGEON, GENERAL INFIRMARY, LEEDS;

AND

R. E. JOWETT, M.D., Ch.B., D.L.O.,

HONORARY AURAL SURGEON, SUNDERLAND ROYAL INFIRMARY;

LATE AURAL OFFICER, GENERAL INFIRMARY, LEEDS.

This paper is a review of over 800 cases of mastoiditis operated on in the Leeds General Infirmary during the past six and a half years. In almost every case the operation was performed for an urgent condition, such as acute mastoiditis, obvious cholesteatoma causing symptoms, or recurrent polypi with pain. On account of the difficulties of hospital accommodation, the simple mastoid operation for the cure of persistent otorrhoea of short standing or the radical operation for chronic otorrhoea has been rarely performed. In all but a few of the fatal cases a report of the necropsy has been available.

For purposes of discussion the cases have been classified as follows:

- 1. *Complicated Cases:* Mastoiditis with, in addition, brain abscess, sinus thrombosis, or meningitis.
- 2. *Uncomplicated Cases:*
  - (a) The simple acute or chronic case which runs a straightforward course.
  - (b) Cases with extradural abscess and no further lesion.
  - (c) Cases of tuberculous mastoiditis.

COMPLICATED CASES.

For practical purposes it can be said that one out of every four chronic, and one out of every nine acute, cases presents one of the above-mentioned complications for treatment. There is little difference in the mortality rate, that in the acute being slightly greater than in the chronic.

TABLE I.—Incidence of Complications in Mastoiditis.

|                                     | Cases. | Percentage of Complicated Cases. | Percentage of Total Cases. |
|-------------------------------------|--------|----------------------------------|----------------------------|
| Temporo-sphenoidal abscess ...      | 46     | 31.0                             | 5.6                        |
| Cerebellar abscess ...              | 27     | 18.4                             | 3.3                        |
| Meningitis, serous and purulent ... | 21     | 14.3                             | 2.5                        |
| Lateral sinus thrombosis ...        | 41     | 27.8                             | 5.0                        |
| C. ... .. 3<br>... .. 2<br>... .. 7 | 12     | 8.5                              | 1.7                        |
|                                     | 147    | 100.0                            | 18.1                       |

Table I illustrates the relative frequency of each complication to mastoiditis as a whole. Fuller details of each complication are given later.

1. *The Meningeal Syndrome.*—Before considering the individual complications it is necessary to comment upon a common manifestation suggestive of infective meningitis, which is nevertheless not necessarily present. Head retraction, vomiting, high temperature with semi-coma and irritability, frequently mask the complicating lesions. Meningeal irritation is undoubtedly present, but whether the condition known as meningitis in the post-mortem room causes it is doubtful. After exploration, even where the cerebro-spinal fluid is milky, some of these cases will recover. Others will be found to have a brain abscess or sinus thrombosis, of which the symptoms were not apparent,

and the prognosis with suitable treatment of these lesions is favourable in a fair proportion of cases. In all such cases the risk of immediate and thorough exploration must be undertaken. In eleven of our cases operations were not undertaken on account of severe meningeal symptoms. Six of these cases were found to have brain abscesses. Purulent meningitis is a rare complication of otitis and mastoiditis in the absence of another lesion.

**2. Brain Exploration.**—In many cases, in the presence of meningeal symptoms and where brain abscess is suspected, one is strongly tempted to explore the brain, but refrains, because of the possible effects of trauma or of sepsis following such a procedure. In such cases an exploratory brain puncture may be the only chance of proving the presence of brain abscess, and it has been found that this operation can be undertaken with only slight risk.

Twenty-seven cases, all presenting meningeal symptoms or symptoms suggesting abscess, were explored with a negative result. Of these, 3 were found *post mortem* to have purulent meningitis; 12 an abscess, with or without other complications; and 3 had lateral sinus thrombosis. Eight recovered, these being probably cases of serous meningitis presenting the masking syndrome. In one the complication present was doubtful. No *post-mortem* examination was allowed. Of the eight cases which recovered, not one showed any effects attributable to brain exploration.

#### BRAIN ABSCESS.

A statistical record of the cases of brain abscess is given in Table II.

TABLE II.—Brain Abscesses.

|                    | Total Cases. | Incidence in Mastoiditis. | Diagnosed. | Suspected. | Not Diagnosed. | Not Opened (Died). | Opened (Died). | Total Deaths. | Death Rate. | Opened (Lived). | Sinus Thrombosis Superadded. | Incidence of S.T. as a Complication. | Acute Mastoiditis. | Chronic. | No Operation. |
|--------------------|--------------|---------------------------|------------|------------|----------------|--------------------|----------------|---------------|-------------|-----------------|------------------------------|--------------------------------------|--------------------|----------|---------------|
| Temporo-sphenoidal | 46           | 5.6                       | 32         | 7          | 7              | 14                 | 15             | 29            | 63.0        | 17              | 7                            | 15.2                                 | 6                  | 37       | 3             |
| Cerebellar         | 27           | 3.3                       | 8          | 9          | 10             | 19                 | 5              | 24            | 88.0        | 3               | 9                            | 33.3                                 | 6                  | 18       | 3             |
| Total              | 73           | 9.0                       | 40         | 16         | 17             | 33                 | 20             | 53            | 72.6        | 20              | 16                           | 22.0                                 | 12                 | 55       | 6             |

Temporo-sphenoidal abscess occurs in about 6 per cent. of all cases of mastoiditis. In this series it has been six times more frequent in the chronic than in the acute cases. Cerebellar abscess, on the other hand, is about half as frequent as temporo-sphenoidal abscess, and occurs three times more frequently in chronic disease than in the acute variety.

#### Diagnosis.

The signs and symptoms in any given case vary enormously, and it is impossible to divide the course of the disease into stages, as has been frequently attempted. Intracranial abscess defies rule-of-thumb methods of diagnosis, and exploration is frequently justified by the presence of one sign or symptom alone. A few notes on the reliability of certain features of the symptomatology are, however, worthy of consideration.

General muscular wasting is a more prominent sign in cerebellar than in temporo-sphenoidal abscess. Cerebral hebetude and irritability are by no means common, but in some cases slow cerebration does occur. The majority of patients are quite rational, complaining only of weakness and loss of physical and mental energy. The semi-comatose condition occurring in the late stages is most frequently seen in association with meningeal signs. Headache of distracting severity is the commonest symptom. It is not necessarily localized, but is often frontal and bilateral. An extradural abscess or sinus thrombosis will cause headache of equal severity, but persistence of this symptom after treatment of such a lesion would justify an exploratory brain puncture. Vomiting is inconstant, is not often effortless, and sometimes occurs after meals, simulating a food vomit. The temperature chart is a most

unreliable guide. A subnormal temperature is rare, and even in the absence of other complications the majority of these cases have a normal temperature or an abnormal one of remittent, intermittent, or continuous type up to 103° F. Much more useful is the disproportion in the pulse temperature ratio, the pulse being frequently ten beats or more subnormal, taking a normal rise in pulse rate of ten beats for every degree rise of temperature as a standard. Optic neuritis is rare, though more frequent in cerebellar than in temporo-sphenoidal abscess.

**Temporo-sphenoidal Abscess.**—The diagnosis of this condition presents less difficulty than that of cerebellar abscess. In only seven out of forty-six cases was the condition definitely undiagnosed, although the signs referable to the nervous system are more indefinite than in cases of cerebellar abscess, and we explain the apparent discrepancy on the ground of the more frequent occurrence of meningeal and sinus thrombosis symptoms in the latter, which symptoms mask the less manifest brain condition. The presence of aphasia of the type in which there is inability to name objects or sounds, for which loss the patient compensates by description, is of great use in diagnosis of left-sided lesions. A fixed, dilated pupil on the side of the lesion is occasionally present early enough to be of assistance in diagnosis. Contralateral hemiparesis is rare, and interference with the motor tracts is not often seen.

**Cerebellar Abscess.**—Examination of the nervous system is of more value than in temporo-sphenoidal abscess. Optic neuritis is more likely to be present. Ophthalmoplegias have not been noted, except the phenomenon of skew deviation, which has only been found in association with semi-coma. Nystagmus is infrequent, but always to the side of the lesion. There is usually atonia with ataxia, and loss of the deep reflexes can be demonstrated. The past-pointing test and the sign known as dysidiadokokinesia have been useful. Marked deafness, which is sometimes found, is an important sign, indicating involvement of the opposite auditory tracts by pressure.

#### Treatment.

The mastoid operation is first performed, either simple or radical according to the indications present. The dura mater is then exposed in either the posterior or middle fossa. In doubtful cases the direction of spread of the bone disease is helpful as an indication which fossa to expose and explore. Frequently a localized pachymeningitis externa or fistula will indicate the spot for exploration. A large-bored Gauvain's needle or a thin-bladed scalpel can be used. In those cases where pus is not immediately evacuated the brain can be explored in several directions to a depth of one and a half inches, and some reliance may be placed on an odour clinging to the exploring instrument after withdrawal, if pus has not been immediately evacuated. Whether puncture is performed in front of or behind the lateral sinus in cerebellar abscesses depends upon the position of the sinus, but for drainage the posterior route is the more satisfactory. If successful the opening in the dura mater is enlarged to admit a rubber drainage tube one-third of an inch in external diameter with a moderate bore, with the end turned back like a flange to make it self-retaining, as advised by Dundas-Grant. Cerebellar abscess is difficult to drain, as the tube becomes blocked with diffident brain matter and there is a liability to kinking of the rubber tube. A medium sized Parker's tracheotomy tube is appropriate by reason of its curve and length, and can be held in position by means of tapes. The posterior wound is closed as far as possible, or lightly packed with gauze. On account of the small opening in the dura mater and bone obtained by this method of access no trouble has been experienced in the way of hernia cerebri.

Speed in operating and a short period of anaesthesia are without doubt essential, but some care must be taken over the ear plastic in the radical cases to give good and easy access to the mastoid cavity for after-treatment. The subsequent dressing of the case when the patient is semi-conscious and refractory is by no means simple, and stricture of the canal must be especially avoided. The drainage

tube has been removed at varying periods after operation from forty-eight hours, and there is still some doubt as to the best time for removal, but until discharge has ceased it should not be removed, and it is better to wait until it is extruded. In one case the tube remained for six weeks without untoward result.

#### Prognosis.

The prognosis of brain abscess is very serious. In our cases the mortality rate for temporo-sphenoidal abscess is 63 per cent., compared with 80 per cent. in the series which was described by Hunter Tod. This figure renders an opinion as to the ultimate result impossible in any individual case, and the chance of recovery seems to be almost as good in the cases with meningeal symptoms as in those without.

In cerebellar abscesses the prognosis is even worse, and in our cases the mortality rate was 88 per cent. Hunter Tod gives a death rate of 90 per cent. This high death rate is explained by: (1) The difficulties of diagnosis (a) on account of the frequent concomitant symptoms of basal meningitis, masking those of the brain lesion, and (b) the frequent occurrence of sinus thrombosis as an added complication. (2) The difficulties in treatment. The cerebellar lesion is more difficult of access and drainage than the temporo-sphenoidal. Of thirty-one cases of temporo-sphenoidal abscess where the abscess was opened and drained, seventeen recovered (55 per cent.). Of eight cases where cerebellar abscesses were opened and drained only three recovered (37.5 per cent.). It is possible that in the future more frequent brain exploration in the doubtful cases will increase the chances of recovery.

#### After-Results.

Attempts to follow up cases of the hospital class are notoriously unsatisfactory. Headache and a mental instability, well described as childishness, persist for some time, but no gross sequelae have been encountered. One case died subsequently of malignant endocarditis.

#### Incidence of Sinus Thrombosis in Brain Abscess.

In our series of cases sinus thrombosis was a concomitant complication in 33 per cent. of the cerebellar abscesses and 15 per cent. of the temporo-sphenoidal. This increased frequency in cerebellar abscesses is explained by the fact that the lateral sinus is a very frequent source of cerebellar infection. This point is of great practical interest in the consideration of the brain lesion, where the symptoms of sinus thrombosis may mask those of the brain abscess, or their urgency result in an insufficient examination of available signs before, during, or after operation. Recovery took place in two of these double lesions. This association may also be expressed by stating that in fifty-seven cases of sinus thrombosis brain abscess occurred sixteen times (30 per cent.). Combined cerebral and cerebellar abscesses have not occurred. Three cases of occipital abscess have been discovered at necropsy.

#### LATERAL SINUS THROMBOSIS.

The incidence of lateral sinus thrombosis, excluding cases with brain abscess, is shown in Table III.

TABLE III.—Lateral Sinus Thrombosis.

Excluding cases with brain abscess, 41 cases. Incidence in mastoiditis 4.9 per cent. Mortality 75 per cent. No cases with ligature of internal jugular vein without exploration of sinus.

|  | Total Cases. | Acute. | Chronic. | Recovery. |      | Death. |      |
|--|--------------|--------|----------|-----------|------|--------|------|
|  |              |        |          | Ac.       | Chr. | Ac.    | Chr. |
| A. Sinus not explored; vein not tied—that is, doubt in ante-mortem diagnosis; S.T. on necropsy | 15           | 11     | 4        | —         | —    | 11     | 4    |
| B. Sinus explored and vein not tied  | 15           | 4      | 11       | 1         | 5    | 3      | 6    |
| C. Sinus explored and vein tied ...  | 11           | 1      | 10       | —         | 4    | 1      | 6    |
| Total ... ..   | 41           | 15     | 25       | 1         | 9    | 15     | 16   |

Lateral sinus thrombosis alone occurs in about 5 per cent. of all cases of mastoiditis, and is more common in the course of chronic than acute disease, although in this relation the difference in incidence is not so marked as in the case of brain abscess. The mortality is 75 per cent.

**Acute Mastoiditis.**—This complication was found in sixteen acute cases, only one of which recovered. The reason for this is found by reference to Table III. In section A are the cases where the sinus was not explored, and the jugular vein not tied. The majority of this class are acute cases. Scrutiny of the records shows us that the majority of these patients were children, and in most the course of the disease was atypical. In such cases the simple mastoid operation was performed for acute mastoiditis, after which the temperature continued to be intermittent and the child to be slightly indisposed. No rigors occurred. In many a perisinus abscess was exposed, but the condition of the sinus at operation was not considered to justify exploration. This exploration was postponed on a "wait-and-see" policy until the onset of bronchopneumonic signs or metastasis proved the true state of affairs, after which treatment was of no avail.

**Chronic Mastoiditis.**—The cases where treatment was directed to the sinus thrombosis are enumerated in Table III, and the results are more satisfactory. These are largely chronic cases. Generally speaking, in the acute case the onus to reduce the mortality rests with the surgeon, in the chronic with the physician. As far as can be judged, in the chronic case the high mortality does not depend so much upon the type of infection or the mode of treatment adopted as upon the delay before these cases come for treatment. In most, a history can be obtained of recent severe prostrating illness; there is not the story of vague indisposition which often precedes the more definite symptoms of intracranial abscess. Most of this series had a history of pyrexia over a long period; many had repeated rigors. It is lamentable that these cases were not sent for treatment, say, after the first rigor, when evacuation of a perisinus abscess would possibly have preceded an uneventful recovery, as has occurred in many cases classed initially as uncomplicated.

#### Treatment.

As indicated above, exploration of the sinus must not be postponed long in those acute cases with intermittent temperature, even though the condition of the sinus, if this was exposed at a previous operation, did not seem to indicate it. Thrombosis can be present in a pulsating sinus which has a normal tunica adventitia. Exploration by incision is the only satisfactory method.

The bulk of the enormous literature on sinus thrombosis concerns ligature of the jugular vein and the indications for it. Recently Laurens has condemned the procedure as unnecessary, and there are grounds for this statement. Inspection of Table IV shows that there is not much difference in the mortality rate between the series in which it was tied and that in which it was not. In our opinion the indications for ligature are few, but can be well defined, and there is no question as to the usefulness of the procedure in cases where these indications are present. The vein should be tied:

- (1) When on exploration of the sinus the clot cannot be entirely removed from the lower end.
- (2) If, after complete emptying of the sinus on exploration, a rigor occurs, or an intermittent temperature persists for more than forty-eight hours.

Ligature or any operative intervention after the onset of the pulmonary signs of pyaemia entails a high operative risk. Two out of three deaths under anaesthesia in this series were such cases.

#### MENINGITIS.

Purulent meningitis, uncomplicated, is the most uncommon complication, and occurred in only fifteen cases—an incidence of 1.75 per cent. "Serous" meningitis was found in six other cases, which were operated upon with good

results. The term "serous" has been used with hesitancy. All these cases had typical meningeal signs and symptoms, and on lumbar puncture a milky fluid was obtained under pressure, which in one case gave organisms on culture. These cases progressed favourably after evacuation of the extradural abscess present. Throughout this paper the aim has been to emphasize a disregard for meningeal symptoms. Whilst accepting the clinical entity meningitis as a terminal stage in extradural abscess, intercranial abscess, and lateral sinus thrombosis, we wish to point out that purulent meningitis alone is a very rare condition in the post-mortem room. Abscesses before rupture can give a clinical picture of meningitis, including a milky cerebro-spinal fluid, and the serous effusion following the irritation of an extradural abscess is accompanied by a similar symptomatology. Comparable conditions can be found in the peritoneal cavity serous effusion with local abscess and a tendency to limitation of extension in the early stages of disease. Nowadays no case of peritonitis is abandoned; similarly the condition which is known clinically as meningitis is an indication for immediate intervention.

#### *Septicaemia and Pyaemia without Sinus Thrombosis.*

These cases described by some authors have been extremely rare in our series. In two cases of septicaemia following operation the subsequent autopsy was negative. In two other cases thrombosis of the jugular bulb was present without changes in the sigmoid sinus, and in one of these cases exploration of the sinus was negative, bleeding being obtained from the lower end. Pyaemia was present in both cases.

Seven cases in the complicated series were probably cases of sinus thrombosis cured by Nature after removal of the focus of bone infection by operation. Each recovered and the sinus was not explored, so that only the clinical course justified a diagnosis of probable sinus thrombosis on account of similarity to those cases of sinus thrombosis which were treated as described elsewhere. Two developed empyemata, one a pulmonary infarction and serous effusion, two had multiple pyaemic abscesses, and two had repeated rigors with a positive blood culture. The lesson learnt has been the necessity for a close watch on the pulmonary condition in cases of sinus thrombosis with pyaemia. Empyemata have been discovered for the first time in the post-mortem room, and the influence which they must have had in bringing about a fatal result can only be conjectured.

#### UNCOMPLICATED CASES.

The mortality rate in the uncomplicated cases is 2.25 per cent. Nine out of a total of fifteen deaths were cases of tuberculous mastoiditis. Excluding these the mortality becomes 0.9 per cent., which is a figure representing the operative risk. One nephritic case died of pulmonary oedema, two rachitic children of acidosis, and one patient of bronchopneumonia. Autopsies were not available in the other two cases. A review of the cases as a whole presents no feature of interest. Under this section two other aspects of the subject are included:

1. *The Prognosis as to Hearing after the Radical Mastoid Operation.*—It has been noticed that the power of hearing is better in those cases with a slight discharge following the radical mastoid operation than in those cases where the cavity is absolutely dry and epithelialized. To obtain a perfect epithelial covering in the cavity it is necessary to curette the inner wall and to cause the formation of a barrier or stricture by scar tissue at the auditory end of the Eustachian tube—with adverse effects on the auditory structures on the inner wall of the middle ear. Most patients with chronic otitis of a severity to warrant the radical operation would be content to sacrifice any usefulness of the ear for hearing for cessation of the discharge. In cases, however, where the function is of importance, the better hearing power of a moist cavity must be borne in mind. These remarks hardly apply to the emergency operation, where the total eradication of disease is indicated.

2. *Streptococcus mucosus Infections.*—A peculiar type of otitic infection was described by Viennese authorities in which the *Streptococcus* or *Pneumococcus mucosus* was found. Several of these cases have occurred, more frequently during the spring epidemic of otitis media. A history of earache is obtained, with or without slight discharge and consequent relief of pain. At a period varying from ten days to six weeks after the onset the patient complains of severe pain behind the ear. On examination a normal or scarred tympanic membrane is seen, with signs of acute mastoiditis, which are frequently atypical. A swelling far back over the position of the mastoid foramen indicates the probability of perisinus suppuration in many cases. Operation reveals extensive bone necrosis and sometimes caries, whilst the bone fragments are soaked in thin pus with a highly characteristic odour. Complications are common. The organism is usually to be obtained in pure culture on account of the absence of a contamination from the auditory canal. Special examination must be made, as it is likely to be mistaken for a common form of streptococcus. It is a member of the group which links together the streptococci and pneumococci, possesses a capsule, is bile-soluble, but occurs in chains. Several varieties have already been classified.

Table IV shows a mortality rate of 14.1 per cent. among all cases of mastoiditis requiring operation, due largely to the high incidence of complications and to the high death rate of such cases.

TABLE IV.—*Death Rate and Gross Complication Incidence in Mastoiditis.*

#### CONCLUSION.

In this paper an attempt has been made to draw conclusions from a series of records frequently far from complete. Every attempt has been made to avoid reference to authorities and to personal views, recording only the lessons and results afforded by the available material. We feel that the subject-matter will be of use to others, because of the better results obtained in the treatment of cases not included here—treatment based on conclusions arrived at whilst this summary has been in progress. Emphasis is to be laid on the following points:

1. The importance of regarding meningeal symptoms as an indication for operative intervention rather than a contraindication.
2. The necessity for brain exploration in doubtful cases.
3. Examination for multiple complications in any complicated case.
4. Early sinus exploration in cases of acute mastoiditis where, especially in children, thrombosis tends to be a "quiet" lesion.
5. The need for education to an appreciation of the danger signal in chronic suppurative otitis media equal to that obtaining at the present time in intra-abdominal disease.

We wish to thank Mr. E. W. Bain for his permission to include case reports and results in the statistics, the staff of the pathological department for their help in autopsies and the like, and the past resident staff of the Leeds General Infirmary, without whose notes this paper would have been impossible.

## Memoranda:

### MEDICAL, SURGICAL, OBSTETRICAL.

#### EPIDEMIC ENCEPHALITIS WITH SEVERE INVOLVEMENT OF THE SPINAL CORD.

The following case, which appears to be one of epidemic encephalitis in which the spinal cord was seriously affected, is of sufficient rarity to be worth recording.

A married woman, aged 31, was admitted into Addenbrooke's Hospital on November 26th, 1923, for loss of sensation and paralysis of the trunk and lower limbs.

**History of Illness.**—The patient was confined on November 9th, 1923, and the child was born without medical assistance. Four days later her bladder became distended, and it had since required daily catheterization. On November 16th she noticed "pins and needles" sensations in her toes; these sensations seemed to pass upwards as far as the level of the breasts, and were followed during the next few days by loss of all sensation from there downwards. At the same time she also had shooting pains at the back of the neck, across the shoulders, and down the upper limbs. During the following days she began to lose power of movement, first in the toes, then in the whole of the lower limbs, and for the last three days she has been unable to move the latter. Two weeks before admission she began to see double, and this has continued intermittently. For about a week she has been very drowsy, being unable to keep awake even when friends came to see her.

**Previous History.**—The family and previous history were of no special importance; she had had four children. Her health had generally been good except for "bilious attacks" and constipation, but six weeks previously she had had an attack of jaundice.

**Condition on Admission.**—She was an intelligent woman, with good complexion and nutrition. Her pupils were normal in size and movement, and ptosis and strabismus were absent. Movements of the eyes from side to side caused pain and slight nystagmus; occasionally diplopia was present. Her hearing was good. The muscles of the face, jaw, and tongue were normal. She complained of pain and stinging at the back of the neck and down both upper limbs; sensation over these areas was otherwise normal. There was a slight loss of power in both forearms, as shown by a weakened grip; the reflexes were increased, but there was no obvious wasting. From about the level of the third rib downwards, over both trunk and lower limbs, there was complete loss of sensation to touch, pain, and changes of temperature. Joint and muscle sense and vibration sense were all absent. There was a small ulcer over the hepatic region from the burn of a hot bottle, and a blister on the big toe from sitting too near the fire, neither being felt at the time; there was a bed sore over the sacrum. The epigastric and abdominal reflexes were absent. The lower limbs were completely paralysed; the knee-jerks and ankle-jerks were absent and the plantar reflexes were extensor. The abdomen was distended and the bowels constipated. The bladder was distended and void of sensation; the urine was acid, specific gravity 1020, and it contained a little albumin and pus. The movements of the chest were diminished, but the heart and lungs were normal. The temperature was 102.8°, pulse 124, respirations 26.

#### Course of the Illness.

On November 28th the patient was very drowsy and fell asleep while being washed. The left knee-jerk was just perceptible. On November 30th lumbar puncture was performed and cerebrospinal fluid removed under increased pressure; it was very faintly opalescent; leucocytes 150 per c.mm., lymphocytes 90 per cent., polymorphs 10 per cent. On culture it was sterile (Dr. W. H. Whittle). Wassermann reaction negative.

On December 1st both knee-jerks very slightly present. Tapping the calf muscles caused extensor response at the ankle-joint. Temperature normal. Two days later she complained of "jumps" in the lower limbs. Right knee-jerk only present; plantar reflexes absent; diplopia less. Could use hands better and feed herself.

By December 12th the temperature, which had fallen since her admission, began to rise again, and was then 103°; this was due to a *B. coli* infection of the urinary tract. For the next two months the patient had a high temperature and was extremely ill, and for several months afterwards she had periodical attacks of pyrexia; with sweating, vomiting, and increased pyuria.

On December 17th she had cramps and pins and needles sensation in the lower limbs; phlebitis of left thigh. On December 23th she was very drowsy in the daytime. Plantar reflexes extensor. The bed sore over the sacrum had become very large.

On January 14th, 1924, sensation was present as low as the tenth dorsal spine. On February 1st the lower limbs were wasted; knee-jerks absent; plantar reflexes extensor. On February 25th the movements of the lower limbs were improving; cramps were occasionally present.

On March 24th the left lower limb was sensitive to touch. Two days later she passed urine normally, the ulcer was healed, and the bowels acted normally. There was occasional incontinence of urine. Abdominal reflexes absent; knee-jerks present, ankle-jerks present; plantar reflexes extensor. She could move both lower limbs. Sensation to touch was present all over the trunk and limbs.

By October 3rd the knee-jerks had increased; plantar reflexes extensor; there was no ankle clonus. On December 15th she could raise both lower limbs off the bed and bend the knees. By January 16th, 1925, she could stand if steadied, and could distin-

guish hot and cold, sharpness and bluntness, over the lower limbs. On February 10th she could walk, if supported in maintaining her balance. Two months later she walked better, but balance remained poor; she had control over bowel and bladder.

Recently the patient wrote to say that she was still slowly improving. She could walk a little with a stick and work about the house, but still had some stiffness and cramps in the legs.

My thanks are due to Professor A. J. Hall, who kindly saw the patient and suggested publication, and to Ward Sister Jones, to whose unwearied attention the patient largely owes her recovery.

Physician to Addenbrooke's Hospital.  
Cambridge.

#### MANGANESE IN FURUNCULOSIS.

The dramatic results often obtained by the use of intramuscular injections of colossal manganese in furunculosis are well enough known, but far less frequently is this preparation given by the mouth. Among children, particularly infants, it is obviously desirable to use the oral method if equally effective. A particular case recently under my care exhibits, I think, a rapid and successful result.

A female child developed, at the age of about 12 months, several boils in the region of the buttocks, with no evident focus of infection. Originally breast-fed, weaning on solid lines had been successful; no alimentary disturbance had occurred, nor was there any reason to suspect any degree of constipation. The teeth were somewhat late in development, but there was no evidence then, or later, of rachitic or other disease. The urine was normal and contained no sugar. Various modifications of diet, bearing in mind especially the question of an underlying disorder of carbohydrate metabolism, were of no avail; local applications were equally ineffective, and for a period of six months crops of boils increased both in numbers and in severity on the buttocks and lumbar region, causing much pain, fretfulness, and irritability.

At the age of 18 months, at a time when several boils, one particularly large, were developing, treatment by colossal manganese was tried, beginning with a dose of 4 minims three times daily in water after food. Within three days the development of these boils was evidently arrested, with hastened absorption of earlier ones. After three days, the dose was increased to 5 minims thrice a day for a similar period; at the end of that time the boils had entirely disappeared, and much of the long-standing induration, the result of repeated crops of boils, had also disappeared. The dose was increased to 6 minims thrice a day for three days, and then to 7 minims for a further three days. At the end of this period—that is, after twelve days' treatment—the area appeared completely normal with the exception of a few bluish patches, the result of some twenty or more old-standing and long-persisting boils. The manganese was then stopped, colossal ferromalt being given in half-drachm doses twice daily after food; this also was well tolerated by the child.

Throughout the treatment no digestive disturbance arose. The general condition improved steadily and fretfulness and irritability ceased. It would seem, therefore, that in the oral administration of this preparation we have a valuable means with which to combat cases such as this, in which no error of diet or of general hygiene seems to have been responsible.

MAURICE L. YOUNG, M.A., M.B., M.R.C.S.  
St. Albans.

#### QUININE POISONING.

A MARRIED woman, aged 28, thinking she was pregnant, procured 60 grains of quinine sulphate in powder from a chemist, dissolved it in hot whisky and water, and swallowed the whole at 10 p.m. She was alone in the house, and at 11 p.m. her neighbours were awakened by her shouting.

For an hour afterwards she was delirious, and had to be held down in her bed. When I saw her, at 1.30 a.m. next day, she was unconscious and in a state of extreme collapse, so much so that I thought death was imminent. However, an enema of hot coffee, a hypodermic of strychnine and digitaline, and hot bottles rapidly produced improvement. At 2.30 she was conscious, but quite deaf; she complained of intense headache, and said she could see nothing. Subsequently she vomited copiously, and afterwards improved steadily.

Thirty-six hours after taking the drug she was walking about, doing her work, and apparently quite well.

The drug appeared to act as a depressant to the respiratory and cardiac systems. I am in doubt as to the amount which may be taken with impunity, but the rapid elimination of the drug is well illustrated by this case.

Stony Stratford. H. GOUGH, M.B.

POISONING BY TOBACCO APPLIED TO  
THE SKIN.

THE cases of tobacco poisoning recently recorded in the JOURNAL remind me of a reference to the condition which is of some historical interest.

Foville (*Influence des Vêtements sur nos Organes*, Paris, 1834) describes the French military headgear of his time as specially tight, heavy, and unventilated. He adds that soldiers were accustomed to carry their tobacco inside their caps, and that symptoms of narcotism often resulted. One can understand that a mass of presumably strong tobacco, confined between an unventilated shako and a moist, overheated scalp, would have much the same effect as the *foscani* in the axilla described by Dr. Deacon (July 10th, p. 61).

## Reports of Societies.

## CONCEALED ACCIDENTAL HAEMORRHAGE.

At a meeting of the Edinburgh Obstetrical Society held on June 9th, with the President, Dr. R. W. JOHNSTONE, in the chair, papers were read by Dr. J. HEWITT and Dr. SAMUEL J. CAMERON (Glasgow) on concealed accidental haemorrhage; Dr. Hewitt described the condition of the uterine wall in these cases and Dr. Cameron discussed the rational treatment, based on Dr. Hewitt's findings.

Dr. HEWITT said that the question of the clinical condition of the uterine wall could best be approached by a brief consideration of the common explanation of the retention of blood within the uterus. He agreed with Gordon Ley that such suggested causes as the non-dilatation of the cervix, adhesion of the membranes around the os, pressure on the lower uterine segment by the presenting part, or rupture of the haemorrhage into the amniotic sac, were inadequate and erroneous. In addition to the objections raised by Ley, Dr. Hewitt quoted Barnes with reference to the supposed adhesion of the membranes, and added the personal observation that in many cases the blood clot was entirely retroplacental. Even when bleeding extended beyond the placental margin, the blood often travelled upwards towards the fundus, and thus never even reached the lower segment. In view of the inadequacy of these theories it was not surprising that the view arose that the blood was retained, because the uterus was unable to expel it, the uterine muscle being described as "inert," "atonic," or "paralytic." Dr. Hewitt's view was that the uterus was temporarily unable to undergo rhythmic contractions, because it was already in a state of sustained and painful tetanic contractions. The basis for this belief emerged from consideration of the question why the foetal parts could not be palpated in cases of concealed accidental haemorrhage. That rigidity of the parietes was not responsible was shown by the fact that palpation still yielded negative results when the patient was deeply anaesthetized, and even after the abdomen had been opened in the course of a Caesarean section on these cases. Intervention of placenta and blood clot occurred in some cases, but in others where palpation had been negative the placenta would often be found on the posterior wall during manual exploration of the uterus in the course of Caesarean section or at a necropsy. He drew attention to the hard, tender, well defined uterus as being incompatible with the description "atonic," and added that in concealed haemorrhage the membranes were tense—a circumstance which could not occur in an inert organ. He referred to the view of FitzGibbon that the apparent increase in size of the uterus resulted from forward projection of the organ, due to its tonic state, but he admitted that in most cases the amount of intrauterine haemorrhage also contributed to the increased size. Sir James Mackenzie's dictum, that a hollow muscular organ might be distended indefinitely without producing pain until a contraction was started, was quoted in support of the speaker's view that the uterus was in a state of tonic contraction.

Dr. CAMERON said it was most important to realize that in concealed accidental haemorrhage the patient's life was endangered more by shock than by haemorrhage. The amount of blood lost in a fatal case was often much less than that lost by patients with placenta praevia who survived. In respect to the relative importance of shock and haemorrhage there was a close similarity between concealed accidental haemorrhage and acute inversion of the uterus. If bleeding was considered to be the more important factor, Caesarean section should be performed on every occasion, but with this Dr. Cameron did not agree; perhaps the most generally practised method of treatment consisted in packing the vagina. It was claimed that an efficient vaginal plug arrested the flow of blood through the uterine arteries, but he did not believe that it was possible by any method short of actual ligature or clamp to arrest or perceptibly diminish the flow of blood through these vessels. Moreover, a liberal blood supply still reached the uterus by the ovarian arteries, which during pregnancy were not much smaller than the uterine, and which, with the latter, formed an unconstricted "utero-ovarian loop" on the margins of the uterus, between the aorta above and the internal iliac artery below. Dr. Cameron demonstrated this point by an x-ray photograph of an injected specimen. In treating cases of concealed accidental haemorrhage the patient should be guarded from shock by administering large and repeated doses of morphine during the acute stage. When this stage had passed, but not before, labour pains were stimulated by pituitary extract. If the patient did not improve after morphine had been given he performed Caesarean section, because in his experience one of two events had occurred—a recurrence of bleeding, or rupture of the uterus. So far he had never been compelled to remove the uterus on account of atony. He did not perform vaginal Caesarean section because: (1) the shock was not less than that associated with abdominal Caesarean section; (2) it was impossible to inspect the uterus for rupture; (3) haemorrhage was less easily controlled; and (4) towards the end of pregnancy extraction of the child might prove difficult.

## Reviews.

## A FRENCH TREATISE ON INSULIN.

IN his volume, *L'Insuline*,<sup>1</sup> Dr. EMILE AUBERTIN of Bordeaux presents to French readers a comprehensive survey of insulin in all its bearings. He has not only collected information from a vast number of published sources, but he has been able to add to this the results of his own and Professor MAURIC's experimental researches and clinical experience. Thus his book ranks as a monograph of first importance in the literature of insulin. The medical profession in France seems to have been handicapped at the outset by the high cost of insulin, the production of which in that country is a State monopoly. For reasons which Dr. Aubertin's book discloses there is no widespread acquaintance in France with the use of insulin in the treatment of diabetes. His work should prove of the greatest value in instructing the medical profession in the administration of insulin, and possibly in creating a public demand in France that the supply of insulin shall be made cheaper and more generally available there.

The book is divided into three sections. The first section deals with the history of the discovery of insulin, its preparation and physico-chemical properties. In the second section the various effects of the administration of insulin are admirably described. This section includes an account of much original work carried out by the author. His observations on the utilization of blood sugar by the tissues are of great interest. He states, for instance, that the sugar diminishes during the passage of blood through the organs of a diabetic just as in those of a normal subject, and that insulin injection does not increase the sugar loss in the diabetic. Yet he admits, of course, that the utilization of the sugar which the blood loses is profoundly influenced in some way as yet unexplained by

<sup>1</sup> *L'Insuline*. Par Dr. Emile Aubertin. Préface du Professeur agrégé P. Mauriac. Paris: Gaston Doin et Cie. 1926. (Roy. 8vo, pp. 420, 23 figures, 45 fr. net.)

insulin administered to the diabetic. He attaches great importance to albuminoids in the production of ketosis and regards them as being more dangerous than fats in this respect.

The third section is devoted to a consideration of the therapeutic use of insulin. Dr. Aubertin, in agreement with his colleagues Mauriac and Piéchaud, has formed the opinion, from their own experience, that the best plan to follow is to adopt a "standard diet" upon which to place the diabetic without preliminary starvation. This diet has a caloric value of 2,800, and contains 240 grams of fat, 80 grams of carbohydrate, and 80 grams of protein. By way of example, charts are given showing patients whose weights were 65, 71, 58, and 54 kilograms respectively at the beginning of treatment. This "standard diet" of 2,800 calories is considerably higher than the 1,679 caloric diet suggested by Woodyatt, which has proved satisfactory in the opinion of so many observers. It will also be seen that the fat-glucose ratio is slightly above Woodyatt's. On the whole, in spite of minor variations, Aubertin adopts the Toronto plan of adequate diet with adequate insulin, and has little to say in favour of preliminary or occasional starvation.

The book is deserving of high praise for the immense amount of literature that has been consulted and condensed into a thoroughly useful summary, while the author and his colleagues have added by their own work fresh and useful facts that materially advance our knowledge of diabetes and its treatment with insulin.

It is a pity that in correcting the proofs so many proper names should have been allowed to remain misspelt.

### HEREDITY.

PROFESSOR ARTHUR THOMSON'S book on *Heredity* has now reached a fifth edition, and is too well known to need any detailed description. Briefly it may be said to give the reader the facts—microscopical, statistical, and experimental—on which our knowledge of heredity rests; it also discusses, in a temperate and fair-minded spirit, the numerous debatable questions inherent in the subject. The tendency to draw far-reaching conclusions in a subject of great importance and naturally engrossing is strong in some natures, and to such the author administers the sobering reflection that it is too soon to settle down to fixed conclusions on more than a few points. The present edition has been revised throughout, and some of the more recent investigations have been incorporated, such as those of Cuénot on Mendelian phenomena in mice, of Haecker on sex differentiation, of Kammerer on the inheritance of acquired characters, and Cunningham's theory of the influence of specific hormones in heredity. An attempt has been made to keep practical problems in view, but owing to the imperfect state of our knowledge it has not been found advisable to risk many concrete suggestions.

The problem of the transmission of acquired characters does not seem to be definitely settled; the practical man, whether physician or breeder, is still in many cases a firm believer in their transmissibility, and one of the keenest physicians has said that a few months in practice was enough to dispel all doubt as to the inheritance of such characters. Professor Thomson, after a thorough overhauling of the evidence for and against, comes to the conclusion that there is little warrant for being other than extremely sceptical about the inheritance of these characters.

With regard to the possibility of the transmission of innate characters and predispositions there is no doubt; as Professor Thomson puts it, it is idle to deny that some children are "born bad" or "born good," and he quotes the dictum of Heine that "a man should be very careful in the selection of his parents." But there is no reason to believe that these inherited predispositions necessarily persist, the probability being that the subtle process of germinal selection is sometimes able to eradicate a morbid tendency. The liability to "rust" in wheat plants is suggestive in this connexion. Crosses between plants that are immune

and others that are susceptible yield hybrids that are all susceptible; but if the hybrids be inbred, the progeny are partly susceptible and partly immune, and the latter breed true—that is to say, the morbid predisposition has been eradicated from them. It is better, however, not to trust entirely to nature in this matter, and the following rules are put forward by the author as deserving of adoption: That the best general constitutions should be mated; that a markedly good constitution should not be paired with a markedly bad one; and that a person exhibiting a bias towards a specific disease should not marry another with the same bias. These rules seem so self-evident that they may almost be regarded as platitudes; they are ignored in innumerable cases, however.

There is less indifference as regards the effects of consanguinity; these are generally understood, but they have latterly been defined with somewhat greater precision. A similar hereditary taint in the lineage of mated cousins is extremely likely to lead to unhealthy offspring, even if the cousins are somatically healthy; and if somatically healthy cousins have what is called a simplex dose of the taint the probability is that one-quarter of the children will be unhealthy. On the other hand, there is no reason why two healthy cousins with a good family history on both sides should not marry. Careful mating, however, can do more than obviate the recrudescence of disease. Karl Pearson's observations lead him to believe that exceptional families can by careful mating obtain an exceptional stock in a few generations; on the other hand, the degenerate inhabitants of the slums of our big cities can as readily produce a degenerate stock, which no change of environment will elevate and nothing but an admixture with better blood will improve.

With regard to the desirability of eugenic measures carried beyond the rules above mentioned, the important fact should be kept in view that our ignorance is, as Professor Thomson states, immense. Some of the recommendations which have been made are merely grotesque, and it is clear that the solution of the difficult problems involved needs to be in the hands of level-headed men, to the exclusion of enthusiasts and hysterics.

### THE SANOCRY SIN TREATMENT OF TUBERCULOSIS.

In a volume written in French Dr. C. H. WÜRTZEN recounts his clinical experiences of sanocrysin in the treatment of pulmonary tuberculosis. He covers much the same ground as his predecessors, spending time on the reactions and the complications that follow excessive dosage. The volume contains two chapters—on variations in antibody response and on morbid anatomy—written by Dr. Hansen and Dr. Fogh respectively. Then follows the history of each patient and a review of the results obtained. Dr. Würtzen divides his cases into three groups. Group I comprises 16 patients that were treated mostly in 1924 and have been followed up after discharge; half of these were mild, half were serious cases; after leaving the sanatorium 7 continued to improve and 9 became worse; one of the latter died of bronchopneumonia. Group II comprises 53 patients treated by 1-gram doses of sanocrysin; the immediate results were as follows: 17, of which 14 were serious cases, died; of the 22 remaining patients 10 showed improvement as judged by clinical and roentgenological examination, 8 showed clinical but not roentgenological improvement, and 4 were frankly worse. Group III comprises 61 patients treated by 0.5-gram doses; of these 8 died, 25 improved clinically and roentgenologically, 24 clinically but not roentgenologically, 2 were unchanged, and 2 were worse. All of the patients except 8 belonged to the Turban 2 or 3 category; of the 8 in Turban 1 only 2 improved both clinically and roentgenologically.

These figures seem to us to be meaningless. That sanocrysin is a dangerous drug there is no question; the fact that 7 out of the 17 deaths in Group II are attributed to the result of treatment suffices to prove this, without

2. *Heredity*. By J. Arthur Thomson, M.A., LL.D. Fifth edition, thoroughly revised. London: J. Murray. 1926. (Demy 8vo; pp. xiv + 542; 47 figures. 21s. net.)

3. *Recherches sur les Effets de la Sanocrysin*. Par Dr. C. H. Würtzen. Copenhagen: Levin and Munksgaard. 1926. (Sup. roy. 8vo, pp. 224; 125 figures.)

mentioning the albuminuria, the dyspepsia, the stomatitis, the anaemia, the haemorrhages, skin rashes, glycosuria, and other complications observed in different patients from time to time. But whether it is of any value it is quite impossible to say—the cases are too few. One of the disadvantages of the clinician is that he sees his patients too closely. He finds it difficult to get away from them and view them with a true sense of relativity; so that when he has recounted the recovery of a few dozen patients he proceeds straightway to draw entirely unfounded conclusions: He is so imbued with the old adage about treating the patient and not the disease that he forgets that it is sometimes far more important to treat the disease rather than the patient. An experimental scientist wishing to ascertain, let us say, the toxicity of a certain preparation, chooses fifty or a hundred animals of the same weight and age, brought up under the same conditions, fed and housed alike, and looked after with the utmost regularity; the dose administered to each is standardized precisely, and a post-mortem examination is conducted on each animal that dies. With these precautions he obtains the percentage mortality due to a certain dose. On repeating his experiment he may obtain a figure differing by 20 or 30 per cent. or even more from his first titration; and not till he has worked out his standard deviation and obtained the degree of variation that is likely to be observed in similar batches injected with the same dose does he feel justified in judging of the toxicity of his preparation. The clinician manifestly cannot do this. His patients are of different ages, are brought up under different conditions, have received varying doses of bacilli at varying times, show lesions differing enormously, not only in their extent, but in their nature, and are dissimilar in a number of other respects. These are treated with varying doses of a drug; some appear to react favourably, others unfavourably. From a consideration of a comparatively few such cases he hopes to obtain a definite answer to his question. The problem he sets out to solve is scarcely clearer than when he started; at the best he is justified in forming no more than the most tentative opinion. It seems to us that the labour expended by clinicians at present is on this account largely wasted. If sanocrysin was capable of affording a rapid and complete cure of all tuberculous patients it might be possible to ascertain this from the treatment of two or three hundred cases; but when, as is abundantly shown, this is not so, the present method of investigation fails. To ascertain the value of the drug it is necessary to treat several hundreds or thousands of patients in the same way, to follow them up for two years at least, and to compare them with similar patients who have received sanatorium treatment alone.

*The Treatment of Tuberculosis with Sanocrysin and Serum*,<sup>4</sup> by Dr. KNUD SECHER, follows much the same lines as Dr. Würtzen's book. Both physicians are working at Copenhagen, and both disagree on a number of important points, such as the value of serum treatment, the dose of sanocrysin to be administered, and the type of patient to whom it should be given. Dr. Secher's figures are frankly worthless; he has selected the ones that he wishes to publish and has omitted a large number of others.

In our opinion neither of these books should have been written. No doubt the desire to publish one's work is strong, but in each case a brief paper in one of the recognized journals would have been sufficient. As it is, the reader is confronted with two volumes of considerable size, from which it is difficult to pick out the essential facts. The tables in Dr. Würtzen's book are too complicated, and, moreover, do not always agree with the text. Dr. Secher's work, which is bravely written in English, is marred by the use of such words as intoxication, bacilli-free, tumorous, and a number of malapropisms and ambiguities of style which render it difficult to read. We trust that in future the devotees of sanocrysin will hesitate before rushing into print in an endeavour to prove what by their present methods is unprovable.

<sup>4</sup> *Treatment of Tuberculosis with Sanocrysin and Serum* (Moellgaard). By Knud Secher, M.D. Copenhagen; Levin and Munksgaard; London: W. Heinemann (Medical Books) Ltd. 1926. (Sup. roy. 8vo. pp. 256; 65 figures. 21s. net.)

## RADIOGRAMS OF THE VISCERA.

*A Descriptive Atlas of Visceral Radiograms*,<sup>5</sup> edited by A. P. BERTWISTLE and E. W. H. SHENTON, adds one more volume to what may be termed the "picture books" on radiology which have been so fashionable in recent years. In a short introduction the chief points of the various organs and regions of the body dealt with are indicated from the x-ray point of view. Following this are over three hundred well produced, and in the main typical, radiograms, which portray very well different x-ray facts to be elicited by the examination of the alimentary, the urinary, the respiratory, the nervous, and the vascular systems. Others deal with the teeth, with foreign bodies, the thyroid gland, the nose, and the female generative organs. Accompanying each illustration is a short explanatory note; in many a short clinical history of the case is provided, and in some cases also the operative findings.

A large number of experienced radiologists have supplied the bulk of the pictorial material. Prominent amongst these are Dr. Rowden, jun., and Dr. Jordan, whilst Professor Sicard, Dr. Spriggs, Mr. Morriston Davies, Professor Wilkie, Professor Fullerton, Mr. Kidd, Sir William Milligan, and others have contributed both radiograms and notes on cases. In addition to abnormal conditions the authors have incorporated a number of pictures of the normal; the latter, in a book written, as this is, more for the general practitioner than the specialist in radiography, add considerably to the book's value. We note also that, although a considerable number of highly interesting rare conditions are shown, the bulk of the illustrations depict the commoner pathological conditions met with in making x-ray examinations. The illustrations are, almost without exception, very good and well chosen, the explanatory notes concise and to the point. The paper is excellent. Throughout there is evidence of the care and forethought of the authors.

Where all is so good it is somewhat inv'idious to pick out for especial praise any one portion, but we consider that the chapters on the respiratory, the nervous, and the urinary systems are the best, and in the latter the illustrations of various kidney conditions, stones and otherwise, by Dr. Rowden, jun., are of great merit. It is one of those books the pages of which it is a pleasure to turn over, and the amount of useful information it contains is very large. To the general practitioner its value will be great, and the specialist in radiology will also find in it much useful information. Not the least interesting point is the price; it is extraordinary in these times that so well and perfectly illustrated a book can be put on the market for the moderate sum of one guinea.

## MODERN METHODS OF FEEDING IN INFANCY AND CHILDHOOD.

THE short book by Drs. DONALD PATERSON and J. F. SMITH entitled *Modern Methods of Feeding in Infancy and Childhood*<sup>6</sup> appears as one of the Modern Medical Monograph series edited by Professor Maclean. It will certainly prove to be a popular book for students because it is concise and dogmatic and expresses opinions in an easily rememberable fashion. The three main subjects dealt with are normal breast-feeding, artificial feeding, and minor digestive ailments of children. The text is accompanied by twelve tables, in some of which there seems to be a good deal of unnecessary repetition. There is not much that is new in the book, as its title might suggest, and certainly nothing revolutionary. Compared with books written on the same subject a generation ago, this short book would differ not so much in its information as in its brevity and emphatic style.

<sup>5</sup> *A Descriptive Atlas of Visceral Radiograms*. By A. P. Bertwistle, M.B., Ch.B., F.R.C.S.Ed., and E. W. H. Shenton, M.R.C.S., L.R.C.P. London: H. Kimpton. 1926. (Cr. 4to, pp. xx + 250; 330 figures. 21s. net.)

<sup>6</sup> *Modern Methods of Feeding in Infancy and Childhood*. By Donald Paterson, B.A., M.B. Edin., M.R.C.P. Lond., and J. Forest Smith, M.R.C.P. Lond. Modern Medical Monographs. London: Constable and Co., Ltd. 1926. (Demy 8vo, pp. ix + 106. 7s. 6d. net.)

## DISEASES OF NOSE, EAR, AND THROAT.

The second volume of the monumental system of otorhino-laryngology, edited by DENKER and KAHLER,<sup>7</sup> forms Part II of the section on diseases of the nose and throat. We published a review of the first volume last October, and it is announced that this section will be comprised in the first five volumes.

Continuing the work on this scale, the general pathology, symptomatology, and treatment of these regions are reviewed in detail, and the reader who desires information on essentials and the selection of the best methods will feel that he is sacrificed to a desire to omit nothing. Thence there is a sudden jump to a description of tracheotomy by Dr. Harmer of Vienna. It seems strange, though perhaps illuminating, that a subject of such vital importance should be illustrated merely by a few blocks depicting tracheotomy tubes, among which Durham's is not seen, whilst a little later in the book a chapter devoted to congenital deformities of the nose is profusely interspersed with an array of frightful monsters, possibly of intense academic interest. This leads on to the subject of hare-lip and cleft palate, and its inclusion in such a work is significant. It is to be noted that Langenbeck's operation for the latter is figured and described, though the operations of Lane and of Brophy are mentioned. It is not easy to understand the plan on which the work has been compiled, for although congenital deformities and tumours of the larynx, trachea, and bronchi follow, there is another sudden change after this to a section on the surgery of the nasal septum, written by the late Professor Passow. This chapter is particularly thorough, and contains an interesting photograph showing the relative position of the surgeon and the patient during an intranasal operation; the surgeon sits on a stool which forms a bridge over the body of the semi-recumbent patient. Dr. Lautenschläger, who contributes a long article on atrophic rhinitis, appears to hold that the outlook is bad and that the reason cases are only seen in early life is that the patients succumb to tuberculosis, pneumonia, and chronic bronchitis, unless they are cured by operation, which he considers the only efficient remedy; he gives no evidence for this gloomy opinion. On the other hand, he believes that the disease sometimes disappears spontaneously in older patients; this certainly does occur, but he is very vague regarding the ultimate fate of these patients. The surgical treatment is described at great length; this indicates a lack of perspective in discussing a disease which readily responds to simple local applications of glycerin containing glucose or honey, a method which is not even mentioned in the ten pages devoted to treatment. The remainder of the volume is almost entirely devoted to the consideration of the inflammatory diseases of the accessory sinuses. The subject is for the most part dealt with on conventional lines, but the chapter on the intracranial complications by Professor Burger of Amsterdam merits attention, as it is clearly the result of much patient research and contains a store of information which can be found nowhere else.

The sixth volume forms Part I of the section on diseases of the ear. Two more volumes will complete this section; the whole system is to consist of ten volumes. This part is arranged systematically, and in this respect is superior to those on the nose and throat; it begins with an account of the evolution and comparative anatomy of the ear. Professor Alexander describes variations and anthropology, and the very complete account of the anatomy of the ear is by the veteran Professor Otto Körner of Rostock. The histological study of the ear, including microscopical technique, and the nervous connexions, conclude the anatomical portion. The next portion is devoted to physiology, and after that come general pathology and therapeutics. General pathology (including injuries) is very full, whilst the article on bacteriology is relatively short but comprehensive. The section on the examination of the ear, by Professor Brühl,

is excellent. It is followed by a description of a method of taking photographs of the tympanic membrane; the results do not appear to be brilliant. The important subject of testing the vestibular apparatus is discussed by Professor Rutin. Towards the end there is an account of lumbar puncture, including the pathological changes which occur in the cerebro-spinal fluid in association with diseases of the ear; it is very thorough and systematic, and is beautifully illustrated. The numerous pictures all through maintain the high standard of the previous volumes; as already noted, this volume compares favourably in the arrangement of the subjects, and the same may be said of the literary material itself. It contains, however, 1,274 pages, and is therefore even more unwieldy as a handbook.

## NOTES ON BOOKS

Dr. FIELDING H. GARRISON has a scholarly style, and rarely has he written more charmingly than in *The Principles of Anatomic Illustration before Vesalius: an Inquiry into the Rationale of Artistic Anatomy*,<sup>8</sup> with the object of supporting the late Dr. Robert Fletcher's view that the real content of artistic anatomy is not descriptive anatomy but ethnic morphology, physiology, and pathology. The principles of pre-Vesalian illustrations of anatomy were, in the first place, slavish obedience to tradition, and therefore faulty rudimentary delineation in manuscript hand drawings and printed diagrams till the time of Leonardo da Vinci; and secondly, admirable first-hand observation of the external configuration of the body, which was more physiological and pathological than descriptive. Conditions such as achondroplasia and endocrine obesity were well portrayed in innumerable Egyptian, Maltese, Pompeian, and Peruvian figures centuries before they received a name. Cubist art is described in perhaps a rather complimentary manner as an attempt to hark back to the childhood of the race and to visualize the feeling of prehistoric and primitive man about the body. The first artist to take to the scientific study of anatomy appears to have been Donatello (1386-1466), but Leonardo da Vinci really founded artistic and physiological anatomy, and possibly his drawings may have suggested to Vesalius the illustrations in his *Fabrica*.

A series of lectures on cardiac diagnosis given to a post-graduate class at Bad Nauheim last year have been printed in a volume.<sup>9</sup> To it Dr. Diethlen contributes an account of the method of estimating the size of the heart by means of x rays. A large amount of work has been done on this subject, but unfortunately it is somewhat contradictory, and the physiological limits of variation in heart size are not yet ascertained with certainty. German and Austrian workers are fairly unanimous in describing a work hypertrophy of the heart, which is seen most clearly in those habituated to long-distance athletic events. Many English and American workers are, however, doubtful of the existence of such a hypertrophy. Dr. Diethlen presents the German view, which appears to be supported by strong evidence based on measurements of the heart shadows of thousands of athletes and non-athletes. He discusses the range of this normal work hypertrophy of the heart, and also gives figures for the normal relation of body weight and heart shadow. Dr. Nickau describes the methods of capillary microscopy, and gives a summary of some of the recent investigations in this field of research, which has attracted so much attention recently. Other writers describe methods for the photographic registration of the venous pulse, the significance of the electro-cardiographic records, and the significance of the shape of the heart shadow in cardiac disease. The articles as a whole give a concise account of some interesting new methods in cardiac diagnosis. Unfortunately in some cases the limits of normal variation do not appear to be clearly defined, and until these are known fairly accurately it is difficult to use any measurement for the diagnosis of disease.

*A Handbook to the Drink Problem*,<sup>10</sup> by WILL REASON, deals comprehensively with the various questions and conflicting statements in a complex controversy. A considerable amount of information is gathered together in the form of questions and answers. A bibliography is provided for further study, and a short index enables reference to be made quickly to the different subjects treated. Lord Aston contributes a characteristic preface.

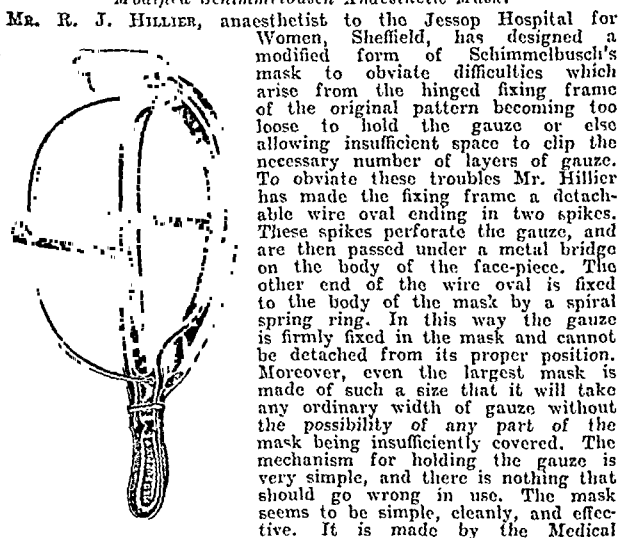

<sup>7</sup> *Handbuch der Hals-Nasen-Ohren-Heilkunde*. Herausgegeben von A. Denker und O. Kähler. Zweiter Band: Die Krankheiten der Luftwege und der Mundhöhle. ## THE HUNTER-BAILLIE COLLECTION.

BY

VICTOR G. PLARR, M.A.,

LIBRARIAN OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AMONG the treasures of the Library of the Royal College of Surgeons of England not the least is the collection of autographs and other documents presented to the institution by the descendants of Matthew Baillie. The collection is in two parts, the first, comprising five volumes, having been presented during the nineteenth century by the late Mr. William Hunter Baillie. With this historic collection, largely incorporated in Lockhart's *Life of Sir Walter Scott*, Douglas's *Familiar Letters of the same*, and Aitken's *Life and Works of Dr. John Arbuthnot*, as well as in several articles in the literary periodicals,\* I am not now concerned. It is the second collection of Hunter-Baillie Papers that claims our attention. This also consists of five volumes, and is of a more personal Hunterian character than its famous predecessors, wherein Pope, Swift, Arbuthnot, Smollett, and Scott occupy much space. The new collection has been beautifully arranged by the donor, Miss Hunter Baillie, the last representative—in some sort at least—of John and William Hunter.

Volume I, which is locked in token of the value of its contents, contains Royal letters and the manuscript poems of Mrs. Anne Hunter, wife of John Hunter.

The so-called Royal letters are, with two exceptions, written by Princess Mary, Duchess of Edinburgh and Gloucester, fourth daughter of King George III. They number some twenty-eight and are addressed to "My dear Baillie" (Dr. Matthew Baillie) and signed simply "Your friend Mary." In every instance they refer to the last illness of Princess Amelia, youngest child of George III, who died of erysipelas in 1810, having been more or less of an invalid since the year 1798. Princess Mary was devoted to her delicate young sister and nursed her to the end. Though often hard to decipher and erratically spelt, the letters are so many careful bulletins of the sufferer's daily progress from July, 1810, to her death at Augusta Lodge, Windsor, on November 2nd of the same year. On July 27th Princess Mary writes: "She adheres strictly [*sic*] to your prescription"; but in August she was already very ill. When dying Princess Amelia presented to the King a

ring, which she had caused to be made. It contained a lock of her hair under crystal, and as she pressed it on his finger she said simply, "Remember me." The aged George III, half blind at the time and enjoying only rare intervals of sanity, was plunged into such poignant grief that he passed into the last sad condition of madness.

Another Royal letter in this collection is in the handwriting of the unhappy Queen Caroline, then Princess of Wales, and refers to her own health and that of the Duchess of Brunswick. "The greatest difficulty . . . consists in persuading the Duchess to listen to an able Esculapius," she writes in her clear Italian script to Matthew Baillie.

An account of the tragic accouchement of Princess Charlotte, dated November, 1817, accompanies these letters. It is unsigned, but appears to be by Matthew Baillie himself.

The poems of Anne Hunter, née Home (1742-1821), who married John Hunter in July, 1771, are interesting as containing the original manuscript of her song "My Mother bids me bind my hair," which was set to music by her friend, the famous composer Franz Josef Haydn. It enjoyed a vast vogue early in the nineteenth century, as appears from Mrs. Susan Sibbald's *Memoirs*. Here also is the original libretto of Haydn's oratorio *The Creation*, in which Anne Hunter displays all her talent for neat and rather trite versification in the late eighteenth century manner. "Of his oratorios," says Sir William Hadow, "the *Creation* alone survives," and his fame rests on his quartets and symphonies. The famous composer set many other pieces of Anne Hunter's to music, but the manuscripts do not indicate this. One may suppose that John Hunter bore with the poetic tendencies of his amiable wife, and that he thus "acquired merit," as did Mr. Salteena in the *Young Visitors* by his marriage. That Anne abundantly appreciated John Hunter is proved by her epitaph upon him in Westminster Abbey, which is here in manuscript. It is, indeed, a noble tribute to a hero of science.

The four other volumes of Hunter-Baillie Papers now under consideration contain an *embarras de richesses*. Here is the original of John Hunter's letter addressed to his brother-in-law, James Baillie, on his being given the degree of Doctor of Divinity and the post of Professor of Divinity in the University of Glasgow. It has been printed by the late Mr. Stephen Paget in his *John Hunter* (Masters of Medicine Series), and bears witness with unaccustomed grace to the great surgeon's domestic felicity four years after marriage. The date is November 20th, 1775. The letter congratulates the divine on his preferment.

"Altho you modestly say it was upon your family's account that you recd. it, yet it is what you should not have refused upon your own. There is hardly any character so low, or so high, but what will receive dignity from Title."

Of his family he says:

"I can only yet say, that I am happy in a wife; but my children are too young to form any judgement of. They consist of a stout red-headed boy call'd Jock [Captain John Banks Hunter, died at Toulouse in 1838], three years and some months old; and a weakly girl call'd Mary-Ann, near two [died in 1776]. We lost a fine boy call'd Jimmy who would have been now about twelve months and Anny is near her time of a fourth [Agnes Margaretta, afterwards Lady Campbell]."

The allusion to the boy's hair is interesting. Hunter's own hair, as appears from the careful miniatures in the superillustrated volumes of *Foot's Life of John Hunter* at present in the Wellcome Historical Medical Museum, was a ruddy auburn, and in the collection now being reviewed Miss Hunter Baillie has preserved in envelopes locks of the fine red gold hair of his infant sister and brother, Elizabeth and Andrew, who died respectively in 1711 and 1714. The baby boy's hair is of unfading brilliancy and beauty and compares singularly with the now fading hue of John Hunter's locks in Reynolds's portrait. One wonders what the little Hunters died of in two successive generations, and in an age of high infant mortality.

"I am not anxious about my children," the letter continues, "but in their doing well in this world, I would rather make them feel one moral virtue" (there is a touch of Rousseau here) "than read Libraries of all the dead and living languages. You

\* See *Edinburgh Review*, October, 1912, and January, 1913: articles by Victor G. Plarr on Walter Scott's unpublished letters to Joanna Baillie.

know I am no *Scholar*, therefore do not feel the beauty of Language when I do not see the use of it."

He speaks of his work:

"As to my studies, I am following my business as a student, pursuing my comparative anatomy; . . . and it appears to be my own enjoyment in seeing me pleasing myself. While all these concurring circumstances go on, I must continue to be one of the happiest of men living."

In connexion with the foregoing self-revelation should be read Joanna Baillie's manuscript notes on the Hunter family, and especially the account of John Hunter's early boyhood, dictated to her by his mother. In this is told the full story of how he mauled a masked "devil," who was one of the Long Calderwood labourers. Of these good people we catch a glimpse in an old letter in Miss Hunter Baillie's private collection of family documents, where a most typical Lowland peasant woman and her *obiter dicta* are described by Joanna Baillie. This old canny peasant must have known the boy John quite well, but is silent on the point. Joanna Baillie, the accomplished dramatist and poet, wrote delightful letters to Sir Walter Scott, which are apparently lost, and to members of her family, of which a number remain. A volume in the collection under discussion contains business letters as to the sale of her books and some unpublished pieces. But the vogue of this woman writer, whom Scott likened to Shakespeare, has too unaccountably passed away.

Among the documents of historic interest here collected mention should be made of the Petition to Parliament, of date 1736, for the purchase of the Hunterian Collection, which is now in the Museum of the Royal College of Surgeons, and the Declaration of Trust relating to the same in 1813. The signatories of both these parchments are Matthew Baillie and Sir Everard Home. Here also is the proposed original Charter of the Medico-Chirurgical Society and the diplomas, burgher tickets conferring freedom of cities, and so forth, of William Hunter. His diploma of membership of the Corporation of Surgeons is dated August 6th, 1747, Chesheldien being among the signatories. Documents and letters relating to the purchase of the Hunterian Museum by the University of Glasgow are also numerous. The date of these is 1783, the year of William Hunter's death.

William Hunter, accomplished and a man of the world, was an industrious correspondent. Many of the letters to him are of historic interest, but are mostly contained in the first part of the Hunter-Baillie Collection. In this new collection we find the following:

"Le lundi, 9 fevrier, [1782]

"C'est avec une veritable satisfaction, Monsieur, que j'ai l'honneur de vous adresser la lettre de M. Amelot qui vous apprendra votre election à une des huit places d'associés étrangers de l'Académie des sciences. Cette compagnie desirait depuis long tems de reparer par la choix d'un grand anatomiste les pertes successives de Morgagni et de Haller, et il y a long tems que les vœux étaient pour vous. Vous voyez, Monsieur, que la guerre qui divisa nos nations n'a nous a peine empêché de rendre justice à vos grands talens. Tous ceux qui come vous concourent aux progrès des sciences et au soulagement de l'humanité ne peuvent être jamais que nos amis. Daignez agréer mes félicitations sur l'honneur que j'ai de vous avoir pour confrere, et les assurances de mon respect, et de mon attachement.

LE MAR. DE CONDORCET,  
Sec. perp. de l'Académie des sciences.

"A Monsieur Hunter."

The famous Condorcet, *encyclopédiste*, friend of Voltaire, and one of the leading wits of the most brilliant society in Europe, is thus seen to have been an admirer of the *Entente Cordiale*. At the time he wrote France and England were still technically at war, for the Peace of Versailles was not signed till September, 1783. William Hunter, he implies, is to be the successor of Morgagni and Haller, but Chopart, in another letter, speaks of him as succeeding Linnaeus, who, however, had died in 1778. Louis XVI actually appointed him to succeed Tronchin. William Hunter died the month after receiving this European honour, and Condorcet was a victim of that French Revolution which he had so laboured to promote.

These last facts lend a certain pathos to Condorcet's cordial letter, written in minute and almost indecipherable script and spelt in the quaint careless manner of his century.

## ST. BARTHOLOMEW'S HOSPITAL WAR MEMORIAL.

THE memorial erected in honour of the 113 students of St. Bartholomew's Hospital who fell in the great war was unveiled on the afternoon of July 8th by H.R.H. the Prince of Wales, President of the hospital. For the purpose of the memorial the archway under the Great Hall, which gives access to the Square from King Henry VIII Gateway and Smithfield, has been reconstructed and beautified. The four panels in this archway and the domed roof, hitherto faced with dingy plaster, have been stripped and recovered with Portland stone, and on the panels have been carved the names of those who fell. Above each of the four panels is part of an inscription. The two panels on one side of the archway bear the words:

THESE GAVE THEIR LIVES FOR KING AND COUNTRY

Those on the other side:

COUNTING NOT THE COST IN DEFENCE OF RIGHT.

The work has been carried out with simple grace from the design of Mr. Edmund Mathews, and forms a most dignified and fitting memorial on a site familiar to every St. Bartholomew's man. Those whose names appear on it served in the Navy, the Army, and the Air Force, the majority as medical officers, some as combatants, and one of them—John Leslie Green, Captain R.A.M.C.T.F., killed in action, July, 1916—won the Victoria Cross. It was appropriate, therefore, that last week's ceremony should be attended by Surgeon Vice-Admiral Sir Joseph Chambers, Medical Director-General of the Royal Navy; Air Vice-Marshal David Munro, Director of Medical Services, R.A.F.; and Major-General Sir Matthew Fell, the newly appointed Director-General Army Medical Service. The Lord Mayor with the Lady Mayoress and the Sheriffs of the City of London were also present, showing the bond which unites the City with the only general hospital within its boundaries.

His Royal Highness was received by Lord Stanmore, treasurer of the hospital, and Sir William Lawrence, Bt., and the other almoners. A guard of honour was furnished by the Honourable Artillery Company. After inspecting these, and a group of ex-service men drawn from the hospital porters, the Prince proceeded to the Square, where the relations and friends of the fallen, the staff, and subscribers to the Memorial Fund, were grouped under a large canopy. Behind them, under the plane trees around the fountain, were a large number of students, nurses, and patients.

A short service, beginning with "O God, our help in ages past," was conducted by the Rev. Dr. A. C. E. Jarvis, C.M.G., M.C., Chaplain-General to the Forces. The lesson, from Wisdom iii, 1 to 10, was read by the Rev. J. L. Douglas, Hospitaller and Vicar of St. Bartholomew's the Less. Sir Anthony Bowlby, Bt., chairman of the War Memorial Committee, and consulting surgeon to the hospital, presented the Prince with a volume, bound in morocco, containing the names and records of the 113 students commemorated, and asked His Royal Highness to unveil the memorial. The Prince stepped forward and drew apart the veil of Union Jacks over the entrance to the archway, saying: "To the glory of God and in honoured memory of the students of St. Bartholomew's Hospital who gave their lives in the great war, I unveil this memorial." A dedication prayer was recited by the Chaplain-General, buglers of the Grenadier Guards sounded the "Last Post" and "Réveille," and the National Anthem was sung. At the foot of each stone panel had been placed a wreath of laurels—one given by the governors, another by the students, another by the council and staff of the Medical College, and the fourth by the League of St. Bartholomew's Nurses.

After the ceremony the Prince made a tour of the Square and spoke to some of the patients who had been brought out in their beds, and on leaving was warmly cheered by the students, nurses, and patients.

## ROYAL SANITARY INSTITUTE JUBILEE CONGRESS.

THE Royal Sanitary Institute Jubilee Congress, the earlier proceedings of which were reported in our last issue (p. 71), continued its work until July 9th, by which time some seventy papers had been read in the various sections and conferences. The addresses of the chairmen of the sections were in some cases very stimulating deliverances, notably that of Sir GEORGE NEWMAN in the Sanitary Science Section, which might be described as an epitome of his previous writing on preventive medicine, and that of Lord EUSTACE PERCY in the School Hygiene Section. Sir GEORGE BUCHANAN addressed the representatives of port sanitary authorities on the international arrangements affecting port sanitary work. The Section of Hygiene in Industry met at the Guildhall, under the presidency of Sir CHARLES WAKEFIELD, who afterwards entertained the members to lunch, when both he and the principal guest, Mr. J. R. CLYNES, M.P., spoke of welfare work in factories and deplored the retardation of progress owing to industrial conflict. Sir Charles Wakefield renewed a previous plea of his for a five years' truce in industry.

*Food and Industrial Hygiene.*

Among other events of Wednesday morning was a session of the Section of Hygiene and Food, at which Professor H. R. KENWOOD spoke on the trade pasteurization of milk—a measure, he said, which served the mutual interests of the trade and the public. With regard to the objection that pasteurization led to a loss of vitamins, he said that only the antiscorbutic vitamin, of which milk was a poor source, could be affected by low temperature pasteurization. All infants, even when fed on raw milk, should be given a little antiscorbutic, such as orange juice.

The Section of Hygiene and Industry was addressed by Mr. J. R. CLYNES, M.P., who spoke on industrial welfare, and by Professor EDGAR COLLIS, who discussed the future of the factory medical service. Professor Collis said that of the two proposals contained in the Factories Bill, 1924—one, to substitute for the office of certifying surgeon the post of "appointed doctor," which meant a practitioner selected by the factory and duly appointed for the examination of young persons previous to employment, and the other, the transfer to the local authority of the duty of arranging for such medical examination—he hoped only the first would become law, since it called upon industry to perform certain health duties, but left industry, under inspection, master in its own house.

*The Health of the Working Girl.*

The Section of Personal and Domestic Hygiene was presided over by Miss ELLEN WILKINSON, M.P., and the principal discussion—on the health of the working girl of from 14 to 16—was opened by Dr. CHRISTINE MURRELL. Dr. Murrell said that in dealing with girls of this age it was important to remember that they were subjected to a double strain in that they had to submit to the conditions required in the labour market while still passing through one of the most vital periods of life. She instanced certain disabilities to which they were liable, such as errors of spinal growth and anaemia, and pleaded for welfare work, the provision of healthy exercises, and a sympathetic understanding of their emotional state. In the discussion which followed, Sir THOMAS LEGER, senior medical inspector of factories, made the remark that in his view there had been a great improvement both in the health and looks of the working girl during the last twenty years. From 30 to 38 per cent. of working girls suffered from anaemia twenty years ago; to-day he would put the figure at 5 per cent. In visiting factories—he noted the looks of the workers, and found that three-fourths of them could be described as good-looking—their features might not be classical, but they were pleasing, and very few were ugly. The discussion widened into the question of the employment of women after marriage, and Dr. LETITIA FARRFIELD, who replied in Dr. Murrell's absence, said that of the women who continued at work after marriage all but a negligible proportion did so from economic necessity, and not from personal preference.

Given proper economic conditions, the question of married women's employment, like other questions, would settle itself.

*Unification of Health Administration.*

Dr. G. F. BUCHAN presided over the Conference of Medical Officers of Health, when the subject of health administration in relation to Poor Law reform and national health insurance was discussed. Dr. Buchan considered that the provisional proposals for Poor Law reform prepared in the Ministry of Health, while not unworkable, did not carry things very much further towards the complete unification of health services. He believed that no solution of the problem of local health administration would be satisfactory which was not based on the principle that in each area there should be one local health authority, and one only, and that each such authority should be directly under the control of the Ministry of Health without the intervention of a third party.

Dr. EUSTACE HILL said that if the views put forward by the Ministry of Health with regard to the transfer to county councils of the sanitary services for rural and small urban districts came to pass he hoped that the county councils would have power to combine sanitary areas in order to get a sufficient unity of population, and that the districts so combined whole-time medical officers of health would be appointed, with control of the whole of the communal health services, including some special services at present undertaken by the county councils themselves.

Dr. H. B. BRACKENBURY made a contribution to the discussion, which was in substance a recapitulation of the arguments put forward in the memorandum on this subject published as an appendix to the Report of Council of the British Medical Association.<sup>1</sup> He contended that there should be a local unification of health administration, not a mere co-ordination of the administrative work of various local public health authorities. The local machinery of administration should involve the establishment by each local authority of a statutory health committee, somewhat on the lines of the present education committees, and every such committee should contain, as a minority, representatives of the medical profession of the area and of other bodies experienced in public health work. In each local area also there should be a representative local medical committee to advise on medical matters. All the services which could properly be regarded as health services should be brought within the purview of one authority in each area. It was particularly undesirable that a county council should be placed in a supervisory or controlling position with regard to large boroughs or urban districts within its area in respect of health matters.

Mr. H. L. EASON (Guy's Hospital) claimed that the general hospital in any scheme should not be regarded as a hospital of second instance—an institution of some sort a patient could go only on the recommendation of free else. He urged two reasons for the continuance of access of the patient to the general hospital—that it was essential that medical students should see all types of disease, trivial as well as serious, and that a voluntary hospital, to fulfil its function as a charity, must provide for the poor person what the rich could afford to pay for—namely, an independent second opinion. Dr. A. E. CORE said that all Poor Law district medical officers and public vaccinators would welcome the increasing co-operation to which the proposed new administration would lead; in the past they had felt themselves cut off from everyone else. Dr. JAMES FENNER (M.O.H. Kensington) dealt with the London problem, and outlined a more even distribution of functions in metropolitan public health administration whereby the London County Council would delegate more of its health functions to borough councils and would remain itself in a supervisory capacity as a kind of provincial board of health for London.

*Jubilee Dinner of the Institute.*

The jubilee dinner of the Institute took place at the Hotel Cecil on July 8th, when, in the absence of the Minister of Health, who was detained by his duties at the House

Commons, the DUKE OF NORTHUMBERLAND presided over a very large and distinguished company, which included the Marquess and Marchioness of Aberdeen, Sir John Gilmour (Secretary for Scotland), and Mrs. Neville Hamberlain. The oratorical feast was on the old-fashioned lines, with eight toasts and eighteen speeches. Dr. CHARLES ORRER proposed "The Health of the Navy, Army, and Air Force," and spoke of the way in which the sanitary aspect had been carried by these services throughout the world. The toast was acknowledged by Surgeon Commander J. L. PISTON and Colonel H. P. W. BARROW.

The Health of Parliament" was proposed by Sir JOSEPH BAKER; and in response Viscount BURNHAM (little knowing that at that very moment an unruly demonstration was taking place in the House of Lords over the Mines Bill) referred to the Upper Chamber as unapproached among legislative assemblies for dignity and courtesy; the nearest thing to it, he said, was the International Labour Conference at Geneva, over which he had lately been presiding. Dr. F. E. FREMANTLE, M.P., responded for the House of Commons, and said that diverse as were the views and interests of constituents they showed a remarkable unanimity when it came to any matter of health. Sir JOHN GILMOUR congratulated the Institute on its jubilee, and Professor BOSTOCK HILL, in responding, paid a tribute to the loyal services, extending over forty years, of its secretary, Mr. White Wallis. The healths of the City of London, of the delegates from overseas, and of the Chairman were also toasted.

## MEDICAL INSURANCE AGENCY.

THE annual meeting of the Committee of Management of the Medical Insurance Agency was held at the House of the British Medical Association, Tavistock Square, on Friday, July 9th, when Sir Humphry Rolleston, Bart., was in the chair, and the following members were present:

Dr. Weaver Adams, Sir Robert Bolam, Dr. Alfred Cox, Lieut.-Colonel R. H. Elliot, Dr. R. A. Gibbons, Mr. N. Bishop Harman, Dr. R. Langdon-Down, Dr. J. A. Macdonald, Sir Squire Sprigge, Mr. W. E. Warne, and Sir Dawson Williams.

### EPSOM COLLEGE.

It was reported that in response to an invitation to nominate a representative for election to the council of Epsom College Dr. R. A. Gibbons had been appointed. It was also reported that the boys whose candidature for election as foundation scholars had been supported by the British Medical Association were all elected. A discussion ensued as to the by-laws of Epsom College limiting the number of votes of any subscriber or donor, and it was decided that the whole question of the future relations of the Medical Insurance Agency with Epsom College should be considered at the next meeting of the Committee.

### CHAIRMAN'S REPORT.

The Chairman, after mentioning that the offices of the Agency had been transferred to the new British Medical Association House in Tavistock Square, continued as follows:

The development of the Medical Insurance Agency has been rapid, if not spectacular, and although it is reflected in the fact that in the past five years the premium income has been doubled, yet it is not only by figures that the growth and influence of the Agency can be measured. One of the best indications of the influence of the Agency is its success in obtaining prompt settlement of claims made on behalf of members. There are occasions, few and far between, when the weight of the Agency cannot in fairness be used, but in the overwhelming majority of cases it is sufficient for the Agency to state that it is satisfied as to the propriety of a claim in order that a completely satisfactory settlement may be effected.

The Medical Insurance Agency set itself a record by introducing over £100,000 of new life assurance business a year, and for five years lived up to that record, but the following table shows how the record was smashed in 1925.

Life and endowment policies were issued through the M.I.A. as follows:

|  |          |
|--|----------|
| Between 1907 and 1920 to the extent of ... | £416,684 |
| During 1921 to the extent of ...           | £105,500 |
| " 1922 " " " ...                           | £113,468 |
| " 1923 " " " ...                           | £101,037 |
| " 1924 " " " ...                           | £113,351 |
| " 1925 " " " ...                           | £160,935 |

—the total since the inception of the Agency exceeding £1,011,000 (one million and eleven thousand pounds).

It must be realized that the income of the Agency from this source will not necessarily be proportionately greater each year, as a much higher rate of commission is earned on new proposals than on renewals, although the office work involved in looking after a life policy, once it has been granted, is, of course, as great in the second and subsequent years as in the first. More and more energy is needed to maintain the rate of progress as the total of the sums assured mounts higher and higher.

A greater number of motor car insurance proposals were received in 1925 than ever before, and there is an increase in the premium income from this source. Despite this, the commission earned shows a decrease. The explanation is that the doctors' special policy introduced through the M.I.A. and underwritten at Lloyd's is being taken up in increasing numbers. The insured pays a lower premium and the commission is calculated at a lower rate on this reduced premium. The Agency loses, but the insured gains.

Although there is a fall in revenue under the heading "Employers' Liability," there is a corresponding increase under the heading "Comprehensive Household Policies," under which domestic servants are also included in the policy.

Efforts have been made to direct the attention of members of the profession to the advantage of sickness and accident policies. It is hoped that this class of protection will become more popular with the profession.

### EXPENDITURE.

It is gratifying to note that the rebates to doctors insuring through the Medical Insurance Agency stand practically at last year's figure, despite the great saving in motor car premiums which has been effected. Had the premiums not been reduced the rebates would have been considerably larger. In this connexion it is interesting to note that the rebates to medical men since the formation of the Agency exceed £22,300, the figures for the last few years being:

|          |        |          |        |
|----------|--------|----------|--------|
| 1919 ... | £360   | 1923 ... | £2,069 |
| 1920 ... | £1,453 | 1925 ... | £2,791 |
| 1921 ... | £1,697 | 1924 ... | £2,811 |
| 1922 ... | £2,064 |          |        |

Grants to medical charities were made during the year 1925 to the extent of two thousand guineas, making a total since 1910 of £14,395 5s., divided as follows:

|   | £     | s. | d. |
|---|-------|----|----|
| Royal Medical Benevolent Fund...          | 4,119 | 10 | 0  |
| Royal Medical Benevolent Fund Guild ...   | 4,148 | 5  | 0  |
| Epsom College ...                         | 3,318 | 0  | 0  |
| M.I.A. Educational Grants Fund (Girls)... | 937   | 10 | 0  |
| Sundry charities...                       | 1,872 | 0  | 0  |

Since rebates exceeding £22,300 have been returned to members of the profession and charitable contributions totalling £14,395 have been made, it may safely be contended that the Medical Insurance Agency is fulfilling successfully two of the functions for which it was formed.

But it is in the unseen, unmeasured work of advice and assistance in the choice of the best policies to meet individual needs, in drawing attention to the absolute necessity to medical men of insurance policies, and in the fair and generous settlement of claims, that the greatest work of the Agency may be considered to be done.

The accounts for the year 1925 have been duly audited by Messrs. Price, Waterhouse and Co., of Frederick's Place, Old Jewry, E.C., whose certificate is annexed to the balance sheet.

The report was approved and the proceedings terminated.

SATURDAY, JULY 17TH, 1926.

## HORSLEY MEMORIAL LECTURE.

SIR VICTOR HORSLEY'S premature death in the service of his country in 1916 removed a pioneer in the science of neurology and in the surgical treatment of nervous diseases. His work will long keep his memory green in the history of the department of medicine which he did so much to advance, and his followers have paid their tribute to his leadership by establishing a memorial lectureship. The first triennial Horsley Memorial Lecture was given on October 25th, 1923, by Professor Sir E. Sharpey-Schafer, on the relations of surgery and physiology, in which he spoke of surgery as based on physiology. The Edinburgh professor had been a colleague of Horsley at University College, and this year the second lecture was given on July 9th by Mr. Wilfred Trotter, senior surgeon to University College Hospital, who was very closely associated with Horsley in his surgical work, and now supplements Sir E. Sharpey-Schafer's contribution by showing that surgery may advance physiology, just as Sir Archibald Garrod, in the Harveian Oration of 1924, set out "The debt of science to medicine." This year's Horsley Memorial Lecture was of the high standard entirely worthy of the occasion, as may be judged by those who will read its full text published in the opening pages of this issue.

In his account of the insulation of the nervous system Mr. Trotter provides his readers—and everyone who did not form part of his audience at the British Medical Association House should take advantage of this further opportunity—with much that is new and stimulating as the products of an original mind. Utilizing his observations as a surgical neurologist on injuries of the nervous system, he throws fresh light on some dark and disputed regions of physiology. From consideration of amputation neuromas and of breaches made in the spinal and cranial dura mater, which allow contact between the nervous and the other tissues of the body, he shows that these are followed by an energetic local reaction resulting in the formation of a highly specialized material and not of a mere scar; in the case of a divided nerve the irritant is the naked axis cylinder, and for the changes in the dura mater the cerebro-spinal fluid is responsible. The insulation of the peripheral nerves is not by the medullary sheath but by the neurilemma which surrounds the sensory axis cylinders everywhere, except at the periphery of the nerves concerned with the perception of pain. This exception has an interesting bearing on the physiology of pain, for the correlation between the anatomical arborescences of pain nerves and the character of painful sensation points to a primitive and crude anatomical and physiological stage. Further, it is shown to be probable that the modifications in all forms of sensation, so as to resemble pain, which characterize regeneration of a cut nerve are a regression of function to the level of perception of pain, and that this regression depends on the non-insulated condition of the nerve fibrils during the process of regeneration. Mr. Trotter makes the attractive suggestion that the cause of von Recklinghausen's multiple neurofibromatosis is absence of neurilemma, so that the non-insulated nerve fibrils irritate the somatic tissues and cause fibrosis, much as

a foreign body or a micro-organism of highly attenuated virulence might.

The central nervous system is insulated as a whole mechanically by the meninges and chemically by the cerebro-spinal fluid, and Mr. Trotter persuasively argues that the function of the cerebro-spinal fluid, which is picturesquely described as "Nature's nearest approach in the animal body to a spring of pure water," is to remove the products of cerebral metabolism and dilute them to a degree rendering it safe for them to pass into the general circulation. The influence of the insulating boundary between the central nervous system and the other tissues of the body is illustrated by the behaviour of intracranial tumours; the neural tumour glioma never invades the meninges or the skull, whereas the dural endotheliomas commonly attack the cranial bones but never the brain.

## THE STANDARDIZATION OF INSULIN.

THE establishment of some accurate standard of potency is the first obvious necessity whenever a new remedy of unknown chemical composition is introduced into medicine. A second and almost equally difficult problem is to secure the general acceptance of a single standard. Standardization is a relatively simple problem when chemical methods are adequate, but biological methods of standardization cannot be avoided in the case of substances of unknown chemical composition, and, indeed, are often needed even when the chemical composition is known. Unfortunately there is no such thing as a standard animal; hence all methods of biological standardization are difficult, and accuracy can be obtained only when tests are performed on a large number of animals. Moreover, even minor variations in methods usually suffice to render the results worthless for comparative purposes; the most rigid exactitude in all details of technique is required to obtain satisfactory results.

No method of biological standardization at present devised, can be regarded as completely satisfactory, and in the past the tendency has been for each country, to set up its own method of standardization, a procedure which results in confusion which is always unfortunate and often actively dangerous. This danger was threatened in the case of insulin, but fortunately the problem has been tackled by the Health Organization of the League of Nations, and it has succeeded in devising an international standard, which it may be expected will meet with universal acceptance. This work was commenced at an international conference on the standardization of drugs held at Edinburgh in 1923, and was continued at a second conference at Geneva in 1925; the conclusions have now been published in a pamphlet.<sup>1</sup>

The first conference agreed that the unit for general acceptance should be similar to that laid down by the Insulin Committee of the University of Toronto. This unit is based on the measurement of the amount of insulin needed to produce a certain degree of hypoglycaemia in rabbits. The conference, however, had to make arrangements suitable for countries all over the world, and recognized that there was little likelihood that a unit so defined would afford the requisite degree of uniformity when applied in different institutions in different countries. For example, the individual variation in the response of rabbits in a single institution is always one of the most serious sources of error, and this error might be greatly increased.

<sup>1</sup> The Standardization of Insulin. Pp. 72. Health Organization of the League of Nations.

by differences in diet, climatic conditions, etc. The committee decided, therefore, to obtain a large quantity of insulin of uniform strength, to determine its strength as accurately as possible in Toronto units, and then to redefine the unit in terms of a weight of the standard preparation. The work involved in carrying out this scheme is summarized in the pamphlet under review.

The British National Institute of the Medical Research Council obtained half a million units of insulin from five different sources in four different countries. This was purified by Dr. Dudley, and was reduced to a dry powder. This powder was assayed in five laboratories in England and America, and the results only varied between 8.4 and 8.8 units per milligram. This accuracy in the results was as satisfactory as it was remarkable. The details in the report show, however, how extensive is the scale of experiment necessary in order to obtain such results. Dr. Clowes of the American Lilly Research Laboratories mentions that from 1,000 to 1,500 rabbits are there used for the assay of a single batch of insulin. The University of Toronto used fewer rabbits, but a preliminary trial on 52 rabbits gave a value of 6.5 units per milligram, while repetition of the test on 200 rabbits gave a value of 8.5.

At the second international congress in Geneva in 1925 it was agreed that the international unit for insulin should be 0.125 mg. of the dry standard preparation, prepared and kept by the Medical Research Council, and that small amounts of this standard preparation should be distributed to all countries desirous of carrying out tests for the standardization of insulin. The conference recommended that in future this should be the only insulin unit used, so that the danger of confusion between the so-called physiological and clinical units may be eliminated. The new unit will be almost identical with the Toronto clinical unit, which has been in use in England for the last two or three years. This unit is about one-third of the original rabbit unit.

The main results of this work of the Health Organization of the League of Nations are twofold. In the first place, a reliable and constant standard has been set up, and in the second place the standard will be accepted generally, so that it will be possible to compare therapeutic results obtained in different countries.

The whole success of insulin therapy really depends upon an accurate method of standardization, and the work under review is a striking example of the way in which an important and difficult scientific problem can be solved by international co-operation.

### KALA-AZAR AND THE SANDFLY.

THE first report of the Kala-azar Commission of India, dealing with the work of the period 1924-25, was published in Calcutta last February as No. 4 of the Indian Medical Research Memoirs,<sup>1</sup> but reached us only in June. The Commission is in reality a twofold one, in that to the Government Kala-azar Commission is affiliated the Kala-azar Ancillary Inquiry, working at the Calcutta School of Tropical Medicine.

The primary aim of the Commission was to elucidate, if possible, the long-debated question of the mode of transmission of the disease. Kala-azar is exceedingly prevalent in Assam, and the headquarters

of the Commission were therefore fixed at the King Edward Memorial Pasteur Institute, Shillong, with a field laboratory at Golaghat. This report reveals the vast amount of work that has been done. Lieut.-Colonel Christophers has written an introductory chapter outlining succinctly the general trend of the numerous papers which follow.

The report proper consists of five parts, to each of which several papers are contributed. The first deals with the morphology, life-history, and bionomics of the Leishmania parasite as revealed in culture. Consideration of numerous questions into which we have not space to enter here seemed to point inevitably to some blood-sucking insect as the intermediate host and vector. Fleas, bed-bugs, reduviid bugs, lice, mosquitos, sandflies, and, of arthropods other than insects, the ticks, have all been from time to time, but mainly on hypothetical grounds, suggested as vectors. Mechanical transmission by non-blood-sucking flies had also to be taken into account. In addition, possible helminthic vectors were carefully considered, and some were tested experimentally. The difficulties were the greater owing to the fact that many of them may harbour herpetomonad forms of flagellates having nothing to do with kala-azar. One example, merely by way of illustration, may be given of the amount of work involved. The previous investigations of Mackie in 1914-15, and of Cornwall in the following year, had tended to reduce greatly the value of the arguments incriminating the bed-bug. Experiments were carried out over a period of fifteen months with twenty-five monkeys (*Macacus rhesus*), and on the death of any animal its organs were thoroughly examined, not only microscopically but culturally, but with uniformly negative results, thus giving a definite quietus to the long-held and plausible theory of the bug as the vector.

The second part of the report details experiments carried out with some other possible vectors. The question of direct contaminative infection, again, could not be thrust aside without adequate testing, nor that of faecal transmission, provided that the parasite could infect by ingestion. Experiments directed to this end were not altogether decisive, though they seemed to suggest that such a mode of infection may be possible. The discovery was next made, by the Ancillary Inquiry, that the parasite readily underwent development in the sandfly, and the Assam Commission, employing *Phlebotomus argentipes*, soon confirmed this. The third part of the report, consisting of eight communications, details the numerous transmission experiments carried out with this insect. The conclusions drawn and stated at the termination of these papers are made with great caution and good judgement. The main difficulty was, not to obtain development in the gut of the sandfly, but the fact that the insect always dies by the fifth day after feeding, unless, as in some instances, it could be kept alive for eight days by preventing fertilization. If death occurs naturally after so short an interval the efficiency of the sandfly as a transmitter is not likely to be great, unless there is a second, more favourable, host to carry on the work. On the other hand, it is also improbable that the parasite should develop as far as it does if this insect is not a true intermediate host. All that can be said at present is that the phlebotomus is very probably the transmitting agent, but the final crucial test of experimental transmission by this insect is still to be successfully performed.

The fourth part consists of four contributions on the *Phlebotomus argentipes*, its morphology, life-history,

<sup>1</sup> Memoir No. 4, Indian Medical Research Memoirs: Supplementary Series to the Indian Journal of Medical Research. Reports of the Kala-azar Commission, India, Report No. 1 (1924-25). Calcutta: Thacker, Spink and Co.; London: W. Thacker and Co. February, 1926. (Cr. 4to, pp. 283; illustrated, 11s. 6d.)

and bionomics, while the fifth and last gives an account of certain epidemiological researches, such as the incidence of kala-azar in various districts, a sand-fly survey of Madras Town, and a most able and informative paper, with carefully considered and cautiously expressed conclusions on the transmission of kala-azar in India from the consideration of the epidemiological aspect, by Dr. L. E. Napier. Among these conclusions it is stated that "every single epidemiological observation appears to be in keeping with the theory that this insect [*Phlebotomus argentipes*] is the transmitter of the causative organism of kala-azar."

This is the stage arrived at in this first report. It needs only the successful transmission of the disease experimentally to place at the summit the coping-stone of the edifice.

### THE INCIDENCE OF CANCER.

REPORTS on the death rate of cancer accumulate, and the stories they tell are fairly concordant. The Department of Health has issued a careful study by Dr. M. J. Holmes<sup>1</sup> of the statistics of the Commonwealth of Australia, and the Metropolitan Life Insurance Company of New York has published a complete analysis of the experience of its Industrial Department<sup>2</sup> from 1911 to 1922. From the technical point of view the American report is the more satisfactory. Tests of the significance of the results from the statistical point of view (perhaps rather too lenient tests) are applied, and the question of age incidence is dealt with more adequately than in the Australian report, which relies too much upon the method of proportional mortality. These, however, are small points, and both studies are useful contributions to knowledge. In a general way the results of the analyses are similar. Thus, according to the American experience, there was no significant increase of cancer mortality (all forms) among white women at any age below 65—in fact, a significant decrease between 35 and 55. At ages over 65 there was a significant increase of 5.2 per 100,000 living in the age group 65-74, and of 14.8 in the age group over 75. The Australian report, although providing the necessary material, does not tabulate the annual rates of mortality in fine age groups. Taking decennial age groups, however, we find that the rate of mortality did not sensibly change between 1908 and 1923 in any age group between 40 and 70, but increased decidedly both in the group 70-79 and in that of 80 and over. In the former the increase was from 607 per 100,000 in 1908 to 854 in 1923, in the latter from 834 to 966. This concentration of increase upon the older age groups seems to be a world-wide phenomenon. The experiences further agree in showing (at certain ages) an increase of cancer of the female breast, and no increase of the rate of mortality from cancer of the female genital organs. Similar results have been found in this country. Both in America and Australia mortality from cancer of the digestive tract is increasing. The American authors remark that 60 per cent. of the mortality from this group of cancers resulted from growths in the small intestine, or in some part of the large intestine other than the rectum or anus. About 31 per cent. of the deaths were due to rectal and anal growths, while 6.5 per cent. were due to cancers in mesentery or peritoneum. Dr. Holmes noted that mortality from cancer of the digestive tract was the outstanding factor in connexion with the increase of cancer mortality in recent years. Having regard to the interest taken in

statistical studies of cancer, it is a pity there is no uniformity of the methods of presentation. Thus it is troublesome—indeed, without special calculation, impossible—to compare directly the results in these two reports. The best way to standardize statistics of cancer is a matter worthy of the consideration of the Health Committee of the League of Nations.

### THE RECENT EPIDEMIC OF SMALL-POX IN FRANCE.

AN epidemic of small-pox of rather severe type, but limited in extent, occurred in France during last autumn and winter. It appears to have begun in the Midi in October of last year, amongst Spanish rag-and-bone men in Toulouse. It spread to l'Hérault and other regions in the south, and ultimately appeared in Paris, being present there from December, 1925, to April of this year. The outbreak did not resemble the comparatively innocuous form commonly termed *alastrim*; in Toulouse the mortality was 25 per cent., in l'Hérault about 33 per cent., and in Paris (where, however, there were only 24 cases) it was 20 per cent. Dr. M. L. Camus, in a paper communicated to the Académie de Médecine of Paris on June 22nd, after pointing out that very few people are immunized for the whole of their life by a single vaccination, said that he was inclined to recommend revaccination every three years. He attributed the long duration of the outbreak in the Midi as compared with Paris to the difference in the energy with which the disease was combated in the two places. To stay an epidemic three measures must at once be rigorously applied: the isolation of those attacked, the disinfection of contaminated places and things, the vaccination without exception of everyone who has come into contact with the patient, and of everyone in offices, manufacturing, or schools to which the patient has had access. In France very little difficulty was experienced in getting people to be revaccinated. Posters were put up, especially at railway stations, calling attention to the danger, and large numbers flocked to the institutions for vaccination. As Dr. Camus expresses it, fear is the beginning of wisdom. Apparently strangers from Tunisia and Algiers are very apt to introduce the disease into France; and Dr. Camus urges that they should be revaccinated before being allowed to leave their own country. Dr. Arnold Netter, at the same session of the Académie, described the epidemics in Switzerland, England, and the United States, which, though very much milder, had, he said, been decidedly more extensive and of longer duration than in France. The evidence from Switzerland is interesting because it shows that the incidence of the disease was much less in the French-speaking than in the German-speaking cantons. In the former vaccination is still obligatory, in the latter it is not. According to Dr. Netter, of the 2,483 small-pox cases in England in 1923, 83.5 per cent. had never been vaccinated, and only 4 per cent. showed recent revaccination. Dr. Netter discusses certain ill effects of vaccination, and declares that violent reaction is not attributable to impurity of the lymph, but to its great activity. With the very active lymph now in use it is considered advisable to diminish the number, extent, and depth of the insertions, although the duration of immunization will not be so long. The eleven cases of tetanus following vaccination in America were due, Dr. Netter pointed out, to the use of protectors analogous to "corn plasters" or "hunion pads."

### PROTECTION OF INFANTS FROM TUBERCULOSIS.

A REPORT by Dr. Paul Labesse on the protection of children in the first year of life from infection by tuberculosis presents an account of what is being done in various European countries as observed in the course of a tour of inspection organized by the League of Nations. Infection in infancy is described in the report as the crux

<sup>1</sup> *Cancer Mortality in Australia: A Statistical Study.* By M. J. Holmes, D.S.O., M.B., D.P.H. (Commonwealth of Australia, Department of Public Health, Service Publication No. 30, Melbourne, 1925.)

<sup>2</sup> *Cancer Mortality among Insured Wage Earners and their Families: The Experience of the Metropolitan Life Insurance Company, Industrial Department, 1911 to 1922.* New York, 1925.

of the whole tuberculosis problem, and the difficulty is only to be met by removing nursing infants from the proximity of infected persons, and especially from the care of tuberculous mothers. In Austria, where good work is being done in hospitals and dispensaries, von Pirquet's reaction is extensively utilized both by its author and by others. Infants exposed to risk which cannot be safeguarded in their own homes are placed with healthy families by private organizations; there are no public services under this head, and no legal sanctions for them. Czecho-Slovakia combats tuberculosis, including the tuberculosis of children, but without special reference to infants. In Hungary an official campaign is carried on, but the protection of infants has little part in it. The infant clinic at Budapest, however, is highly efficient, and suitable cases are sent to a lakeside sanatorium. France is the scene of much activity. Nurslings are withdrawn from infective surroundings. A special feature is ante-natal prophylaxis; if an expectant mother is discovered to be suffering from tuberculosis she is warned that her child must be removed from her care at birth. There is good co-ordination between infant centres, hospitals, dispensaries, and other charitable foundations. The work in general is under voluntary agencies, and is only subsidized from public funds through indirect channels. In Belgium the co-operation between infant welfare and tuberculosis control is weak. There is open-air treatment for the tuberculous at Knock and elsewhere, but young infants are excluded. Holland takes an interest in the welfare of infants and in tuberculosis prevention, but there is little to report in the way of results, especially under school age. In Switzerland the idea of infant protection from tuberculosis has, it is said, taken a firm hold. The crèches at Neuchâtel accept the charge of infants from tuberculous families. The Lausanne dispensaries give special attention to infants exposed to risk, and tuberculous meningitis has become rare in the district. The countries reported on thus fall into three main classes. In the first class are Austria, France, Switzerland, and probably Hungary, where there is much local enterprise by medical charities and other private agencies, but without official recognition or without the effective form of recognition which is expressed by grants-in-aid. In the second class are Czecho-Slovakia, Belgium, and Holland, where nothing definite appears to be done for the infant exposed to tuberculosis. In the third class, by itself, is England, where the nursing at risk, though not specially marked for attention, is nevertheless protected, since it shares in the general well-being. Having regard to the situation as summarized above, the report expresses regret that the policy of protecting infants from tuberculosis by removing them from infected persons does not in general receive that position of honour which it is held to deserve. Its effective application, it is claimed, would strike at the root of tuberculosis. It would reduce infantile mortality by 30 per cent., being the proportion of tuberculosis deaths to total deaths in the first year of life. This proportion of 30 per cent. of tuberculosis deaths, which is quoted in the report from an American source, is unduly high if judged by British standards. It is open to doubt whether the reduction in the number of tuberculosis deaths under one year likely to ensue on the adoption of an intensive removal policy, even assuming the complete success of that policy in securing the object aimed at, would approach the figure suggested. The claims of the report, therefore, under this head appear to be overstated. Some of the tuberculosis developing in the early years of life succeeding the first must, and much of it may, be due to infection in infancy by either the human or the bovine type of the tubercle bacillus. The tuberculous mother, probably phthisical, would, as such, almost invariably harbour and disseminate the human type of bacillus, so that the removal of her infant from

her care would certainly protect it to that extent from infection by the human type. But other forms of tuberculosis contracted in the first year, of which tuberculous mesenterica and glandular tuberculosis in early childhood may be cited as examples, are frequently of the bovine type, and the young infant, by being removed from its mother, would not necessarily be protected from them. Wherever bovine infection is prevalent the child would be subject to that infection in its new home as in the old, excepting in so far as its new environment might be more hygienic and its milk selected or pasteurized. It is asking too much of a method which is mainly directed against the human type of bacillus that it should also repress the bovine strain, which infects through a different channel. It is not intended by these remarks to depreciate the policy of infant protection by the methods now under notice. At Lausanne it is claimed to be justified by its results. At least it has been attended by a remarkable decline in the incidence of tuberculous meningitis, usually a human type of infection. As an item in a well organized tuberculosis scheme it has an obvious value. But however actively carried on it is, in the presence of bovine infection, only a partial defence. It cannot supersede other well known methods. The removal of an infant from its tuberculous mother will have served little purpose if the child is immediately afterwards infected by milk from a tuberculous cow. The English plan, to which the report refers, of making provision for infant protection from tuberculosis as a part of a general movement, shows practical sense and is apparently not ineffective. Balance as well as co-ordination must be observed in working out these measures. The protection of infants from tuberculosis by withdrawing them from contact with infected persons, and especially from the care of infected mothers, must surely be looked upon as a link in the chain, and not the chain itself.

#### TUBERCULIN TREATMENT OF TUBERCULOSIS.

OUR attention has been called to an error in an answer we gave on July 3rd (BRITISH MEDICAL JOURNAL, p. 47) to "Tuberculosis Officer," who asked if any investigation had been made by the officers of the Ministry of Health into the treatment adopted by Dr. Camac Wilkinson at his tuberculin dispensaries; and if so, what was the verdict as to the efficacy of the treatment. We stated that an inquiry was made in 1923, at the request of the Ministry of Health, by the Medical Research Council; but that "the report of the visitors was not, so far as we are aware, published, and was described as confidential." It appears that there were several errors in our answer. The inquiry took place as the result of a letter to the Right Hon. Christopher Addison, then Minister of Health, from the Tuberculin Dispensary League. The Medical Research Council asked Drs. G. T. Western, L. S. T. Burrell, and A. S. MacNalty to conduct the investigation. They reported early in 1921, and for a time the report was regarded as confidential. But owing to the publication of Dr. Camac Wilkinson's pamphlet, *The Tuberculin Dispensary for the Poor*, in the summer of 1923, the Medical Research Council consented to the publication of the report, which appeared in the issue of the *Lancet* for November 3rd, 1923 (p. 984). The conclusions reached by the committee were: That the evidence submitted by the Tuberculin Dispensary League was not as full and satisfactory as was desirable; that the method immunized patients to large doses of tuberculin, but that there was no evidence that it immunized them to tuberculosis; that the most favourable results related to Stage I (Turban-Gerhardt) cases, but that it could not be assumed that these patients were treated solely by tuberculin; that the mature age of many of the survivors was indicative of a chronic type of pulmonary tuberculosis, and that equal longevity could be

seen in cases untreated by tuberculin; that occasionally individual patients derived distinct benefit from tuberculin treatment, but that there was always the risk that large doses of tuberculin might light up latent foci of the disease. For these reasons the investigators were of opinion that the method of tuberculin administration advocated by the Tuberculin Dispensary League had no claims over other methods of treating tuberculosis which would justify its general adoption.

#### THE REBUILDING OF "BART'S" IN THE EIGHTEENTH CENTURY.

SIR D'ARCY POWER has contributed to *St. Bartholomew's Hospital Reports* a paper, "The rebuilding of the hospital in the eighteenth century," from which it appears that even the two large volumes of Sir Norman Moore's history do not tell the whole story. In 1723 a general court decided on rebuilding some part of the house, and appointed a committee, among whose members were Drs. Mead and Freind and the architects Nicholas Hawksmoor and James Gibbs, with instructions to prepare a plan. Both these architects have left their marks on the church buildings of London. Both of them were steeped in the Wren traditions, and especially Hawksmoor, who was the scholar and domestic clerk of Sir Christopher. The two took a large part in designing and building the fifty new London churches at the close of Queen Anne's reign, but Gibbs's greatest claim on the interest of the medical profession, especially of its London consultants, rests on his building of St. Peter's, Vere Street, a church which has a peculiar connexion with the medical quarter and in which the funeral services of many of the great ones of medicine and surgery have been held. These two artists freely gave their services to St. Bartholomew's, and Gibbs in particular gave his designs and supervision to the work of rebuilding. Neither of them could produce anything to rival Wren's best work, such as the steeple of St. Mary-le-Bow, and in the heyday of the Gothic revival their work was despised as dull and heavy; but in these days, when even the baroque style has its enthusiastic admirers, we are once more allowed to find beauty in the work of the followers of Wren. But a more interesting person than either of the architects was soon added to the court in the person of Ralph Allen of Bath, the Squire Allworthy of *Tom Jones* and the host and benefactor of Fielding and of Pope and of many others. The former has immortalized his friend in "that exquisite picture of human manners," and the latter, in his *Satires of Horace*, wrote:

"Let Humble Allen, with an awkward shame  
Do good by stealth and blush to find it fame."

Allen, after making a princely income by reforming the postal services, became still wealthier as the proprietor of quarries near Bath. In the *Dictionary of National Biography* it is stated that "he cased the exterior of St. Bartholomew's Hospital in London with stone at his own expense." Sir D'Arcy Power shows that this statement is inaccurate. Allen was an open-handed philanthropist, but he was enabled to become so by his keen business instincts and methods. He frankly told the authorities of St. Bartholomew's that his offer to supply the stone at a low price was inspired by a desire to get his stone known and to form a market for it in London. As things turned out he must have lost a great deal of money by his contract. The stone was conveyed from the quarry to barges on the river Avon, and then by water to Bristol, where it was put on shipboard for the sea voyage to London. All went well with the building of the first and second piles of the new structure, but soon after the third was begun the war of the Austrian succession broke out, and the risks to shipping were very grave. Even when Allen bought a quarter of

a ship the press-gang and the temptations of service in privateers made it difficult to man her, and enemy action rendered the voyage dangerous. Finally, the ship was cast away, to Allen's loss. These and other causes delayed the work, so that the rebuilding was not finished till 1752, when the inscription over the inner gateway of the hospital was set up, but a later addition to this inscription stated that it was finished in the year 1770. Last year the members of the British Medical Association who attended the Annual Meeting at Bath had opportunities of seeing some of the results of Allen's philanthropy in the building of the Royal Mineral Water Hospital, as well as the magnificent home which he built for himself at Prior Park. Another great man and governor was William Hogarth, who was born in Bartholomew Close, and whose paintings on the walls of the great staircase are familiar to all visitors to the hospital. He grasped at the opportunity of showing his powers in the great style of history painting, and, as he said, "with a smile at my own temerity, commenced history painter," with "two Scripture stories, the 'Pool of Bethesda' and the 'Good Samaritan,' with figures seven feet high." But the public knew better than he did in what style of painting he most excelled, and, as he said, he "returned to the pursuit of my former dealings with the public at large." We are glad to note that this paper is only an instalment, and we look forward to the continuation which Sir D'Arcy Power promises to us.

#### MINER'S NYSTAGMUS.

THE committee appointed in 1920 by the Medical Research Council to investigate the causation and means of prevention of miner's nystagmus announced in the following year its unanimous conclusion that the essential factor in its production was deficient illumination. This was ascribed to the low lighting power of safety-lamps, their distance from the objects looked at by the miner, and the absorption of light by the dark surface of coal. The committee recommended by way of prevention that the standard of illumination of objects, in all places where work was done, should be made equal to that of open-light pits, either by increasing the power of safety-lamps or by the introduction of portable electric lights. The personnel of the committee commanded respect: their investigations covered an extensive field, and the conclusions reached were broadly supported by the data they brought forward. It appeared to many that the etiology of miner's nystagmus had found at least a provisional explanation, and that time should be given for the proposed remedial measures to be put to the full test of experience. It is therefore noteworthy that an ophthalmologist of the standing of Dr. Freeland Fergus of Glasgow, who is familiar with miner's nystagmus as a referee, should have stated recently<sup>1</sup> that the nystagmus committee, in his view, went on wrong lines, and that the remedy suggested has only made matters worse and put owners to great and needless expense. The change from the safety-lamp to electric light, he says, has in certain pits increased the number of cases of nystagmus: he even quotes one pit by name where the nystagmus rate rose when the safety-lamp was given up, and fell again on its reintroduction. He contends that miner's nystagmus is chiefly a disease of the nervous system. Though its cause, so far, is undiscovered, he does not regard it in any sense as within the province of the ophthalmologist; he hands on the problem to pathologists, neurologists, and medical officers of health for exploration in their several departments. In laying stress on the nervous factor Dr. Fergus does not seem to be really at variance with the reports of the nystagmus committee. It described the eye movements as but one among the manifestations which go to make up the symptom-complex; neurasthenia, or neurosis

<sup>1</sup> *Glasgow Medical Journal*, March, 1926.

with sleeplessness, anxiety and mental depression, were, the committee said, present in the later stages. The committee cited as modern views of the disease that it may be either an oculomotor fatigue or a general neurosis with local oculomotor involvement, clearly contemplating that in certain cases at least it may be chiefly a disease of the nervous system. With regard to the utility of brighter illumination for the prevention of nystagmus the divergence between Dr. Fergus and the committee is complete. If it has been made manifest by the trials made—assuming that these have been sufficient in number, extent, and duration to warrant a definite conclusion—that lighting is no remedy, it follows that the industry should not be asked to bear further charges for lighting reconstruction. If lighting is no remedy it follows also that deficient illumination cannot be the essential factor in the causation of miner's nystagmus, and the whole question remitted to the nystagmus committee is reopened from the beginning. The facts as to the results of the lighting improvements will doubtless be made known when available. Meanwhile Dr. Fergus himself has been pursuing inquiries, and has obtained statistics which he hopes to publish before long. Their appearance will be awaited with interest.

#### A LABORATORY FOR THE STUDY OF MENTAL ABNORMALITY.

SOME years ago Dr. Arthur MacDonald drafted a bill "to establish a laboratory for the study of the abnormal classes," which has been endorsed by many leading medical, legal, and religious organizations in the United States, and also by the International Congress of Criminal Anthropology of Europe. This bill was twice reported upon favourably by the Judiciary Committees of both Houses of Congress, but failed of passage through delay. Dr. MacDonald ceased to press the bill in Congress, but owing to the increase of these evils, which it is the purpose of the bill to prevent or lessen, he considers it high time that a rigid scientific study of the individuals producing these evils should be instituted by the Government. He points out that the cost of these antisocial personalities to the United States is more than one billion dollars a year, including all patho-social activities outside of institutions, not to mention the still greater moral damage involved. The proposition is to spend \$110,000 per annum to combat this enormous annual drain upon the American people by the latest methods known to science. The main purpose of this bill is to provide for the study of the causes of crime, insanity, pauperism, alcoholism, defectiveness, degeneracy, and other forms of abnormality, with a view to lessening or preventing them; but in addition to this general scope of the bill there are some other direct ends which it is expected to accomplish. Such ends are to discover whether or not there are any physical and mental characteristics that distinguish abnormal from other children, with a view to protecting children in advance; to undertake the exhaustive study of single typical criminals in order to determine how men come to go wrong, and to what extent their surroundings influence them as compared with their inward natures; to summarize and combine results already gathered by State and Federal institutions, encouraging uniformity of method in collecting data useful generally to all States; and to lessen the enormous expense to the community of the abnormal and delinquent classes by a study of the evils which lead to such expenditure. Dr. MacDonald is of the opinion that the acquisition of proper and full statistics would in itself justify the bill which he proposes. A similar suggestion was made by Professor Kraepelin, who maintained that psychiatric investigation on a large scale is necessary to determine whether the general tendency of civilized communities is towards decadence on the one hand, or progressive development of

productive and resistive power on the other. We need what he describes as a "mass psychiatry," having at its disposal statistics in their widest scope, to provide the foundations for a science of mental health—a preventive psychological medicine for combating all those mischiefs which we group under the head of mental degeneracy. We shall watch with interest further developments in connexion with this bill, which appears to have the support of those best qualified to estimate its social significance. It would certainly seem that a laboratory such as the author describes would be of considerable service to the community.

#### THE ROSS INSTITUTE AND HOSPITAL FOR TROPICAL DISEASES.

IN anticipation of the opening by the Prince of Wales on July 15th of the Ross Institute and Hospital for Tropical Diseases at Putney Heath, Sir Charles McLeod, chairman of the council of the institute, Sir Ronald Ross, director-in-chief, and the members of the staff gave a reception last week to a number of journalists, to whom they explained its methods and purposes. Since the appeal for a Ross clinic was made, above the signatures of many eminent persons, in 1923, a good many disappointments have been experienced in the endeavour to acquire a suitable building. If the public dislike the proximity of an ordinary hospital, the idea of a hospital for tropical diseases appears to evoke still greater objection. Eventually, however, the freehold was secured of a modern mansion known as Bath House, standing in its own grounds of two and a half acres, on the border of the famous heath where nowadays the highwaymen and gibbets are scarcely a memory. A good deal of structural alteration within and without has been necessary, but the result is a beautiful as well as a convenient building, and not often do the windows of laboratories look out upon such refreshing views. The purpose of the institute, as explained by Sir Charles McLeod, is primarily intensive research work on the prevention and treatment of tropical diseases, but it is also to serve as a hospital (in a small way, at all events at first) for sufferers from such diseases, and as a propagandist centre for stimulating and assisting control work in malaria and other diseases of tropical countries. It is hoped that the institute will take its place in that little group of institutes in various parts of the world which in their name commemorate a distinguished pioneer, such as the Pasteur Institute in France, the Gorgas Institute at Panama, and the Kitasato Institute in Japan. Sir Ronald Ross told the assembled journalists that although, by the wish of the council, the institute bears his name, its inception was not due to any idea of his own. In 1917 Dr. Aldo Castellani, who is now director of tropical medicine and dermatology at the institute, came to him with a proposal to raise a public subscription to found a Ross clinic with laboratories. The preoccupation of the war prevented the idea from being carried further at that time, but later on Dr. Castellani renewed his suggestion, and with Sir William Simpson, now the institute's director of tropical hygiene, worked out a plan. In response to a public appeal many contributions were received, especially from companies interested in tea and rubber plantations in the East, and also from Governments and municipalities of British possessions, and from Indian princes and others. It was proposed, among other subjects, to carry out researches on cancer and small-pox. The object of the institute is to assist generally in the control, prevention, and cure of the diseases, especially malaria, which lay waste the tropics, and it is hoped to raise an endowment fund of a quarter of a million. The visitors were then taken over the laboratories of Sir Ronald Ross and his two colleagues, Sir William Simpson and Dr. Castellani, and were also shown the library of tropical diseases which is in course of formation, and the nucleus of

a museum, which includes the microscope used by Sir Ronald Ross when, in 1897, he discovered the transmission of malaria through the anopheles mosquito to human beings. The method of breeding mosquitos for experimental purposes at the institute was also demonstrated. The attached hospital consists of twelve beds, two of them already occupied. It was stated that medical men home from the tropics have already taken advantage of the facilities offered in the laboratories, and have done research work on their own account at the institute. It is intended that reprints of papers relating to work in which the institute has had a share shall be circulated free to doctors abroad whose names are sent forward by subscribers and others, but the point is made that this is not to be a teaching centre, and that its purpose is to supplement, not to compete with, the existing schools of tropical medicine.

#### THE PUBLIC HEALTH ADMINISTRATION OF JUGO-SLAVIA.

DR. ALFRED GREENWOOD, county medical officer of Kent, was nominated nearly a year ago by the Ministry of Health as one of two representatives from England to visit Jugo-Slavia and study its public health on behalf of the League of Nations. He has now issued to his county council a report on what he saw there, and for readers here it will serve the same purpose as the memorandums for various other countries, including Germany, Austria, Hungary, and Czecho-Slovakia, already issued direct by the Health Section of the League's Secretariat. That regarding the Kingdom of the Serbs, Croats, and Slovenes was noticed briefly in our issue of October 24th, 1925 (p. 760), but Dr. Greenwood's report on the same area hardly overlaps it, and is worthy of separate attention. Instead of dealing in sequence with the many subjects now embraced in the wide sphere of public health, Dr. Greenwood has in very interesting fashion adopted the style of a narrative of his perambulations of the country, telling brightly and briefly what he saw of health organization, institutions, and activities wherever he went in his travels, which extended over a period of six weeks. French was the medium of communication between the different nationalities represented on the tour. The costs were borne by the Rockefeller Foundation. Jugo-Slavia includes what was formerly Serbia as its largest component part. After explaining the international exchanges in public health of which the expedition to Jugo-Slavia formed a part, Dr. Greenwood gives a short but clear and interesting history of the peoples covered by the geographical expression Jugo-Slavia, the "land of the South Slavs," descended from tribes settled in the North-Western Balkans after the fall of the Roman Empire, who were for long divided by physical barriers and by forms of religion. The present kingdom has an area of 96,000 square miles and a population of over twelve millions. Serbia lost a million men in the war, and had only 1,600 doctors at the end of it. Now there are 3,000 doctors, or 1 per 4,000 of population, so that there is still ample room for increase of medical personnel. Following such preliminary information Dr. Greenwood proceeds to tell the story of his tour, which he divides into three parts. In the course of it he gives a brief account of all the health institutions and activities of the country. In that account we do not propose to follow him, but may note that it embraces the passing of a National Health Insurance Act in 1922, under which dependants as well as workpeople are included. The report naturally contains many criticisms, but Dr. Greenwood rightly claims that these are constructive, not destructive, and he holds up to admiration "the excellent public health work which has been carried out in Jugo-Slavia in such a short time."

#### ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE eighty-fifth annual meeting of the Royal Medico-Psychological Association was held in London, at the British Medical Association House, from July 13th to 16th. The association during the year has had to mourn the death of its president, Sir Frederick Mott, and an eloquent tribute to him was paid by the acting president, Dr. M. J. NOLAN, who described Mott as one of the vital forces of the association. Dr. J. R. Lord, C.B.E., was elected president for 1926-27. Dr. C. Winckler of Utrecht and Dr. Adolf Meyer of Baltimore were elected honorary members, and Dr. Edwin Goodall of Cardiff was nominated Maudsley lecturer for next year.

##### *Clinical Study of Mental Disorders.*

Dr. J. R. Lord's presidential address, on the clinical study of mental disorders, was really a volume, running to seventy-eight octavo pages, and will be published in full in the *Journal of Mental Science*. He began by dealing with the purposes of the association, and urged the re-establishment of a research committee whose functions would include the definition of psychological and psychiatric terms, and the collection, registration, and classification of clinical data. A sounder knowledge of the psychic processes underlying the disordered mind called not only for research work, but for properly organized and routine team work in the investigation and treatment of individual cases. Individual treatment alone, however much concentrated, would never cure mental disorders. Team work meant a concentration on the individual case by several doctors, one of whom should be foremost and responsible. He then reviewed the special departments of knowledge which psychiatry needed for its clinical purposes, the first of these being psychology. Here he considered that the psycho-analytical conceptions of Freud and his school, and their modification by Adler and others, had been a distinct gain to psychiatry, especially in the sphere of psycho-pathology, giving it a new vigour and quickening the interest of the profession and of the community generally in psychological matters.

The President next considered the more important of the psychological approaches to the problems which concern clinical psychiatry, showing that they were all of service in one relation or another, after which he went on to speak of the physiological and biochemical approaches in the same way. In the province of pathology and psycho-pathology two principal schools had grown up—namely, the physiogenic and the psychogenic. The wards and laboratories of the mental clinics and hospitals afforded one ground at any rate for a closer approximation of the work of both. The progress of clinical psychiatry had been held up by dissociating the mind from the body, or the nervous system from the body, and by neglecting sociological considerations. The aim of such team work as he advocated was to supply the psychiatrist responsible for the diagnosis and treatment of a case with a complete clinical picture, taking advantage of every avenue of approach, physiological and psychological alike. Clinical psychiatry, he said, could not take up an *ex parte* attitude in respect of the factors operating in the case of mental disorder, and must, as far as possible, dissociate itself from leaning towards any one viewpoint, or one of the main objects of team work would be defeated. Clinical psychiatry had for too long suffered from such one-sided investigations, culminating in the accumulation of much unbalanced knowledge about mental disorders and diseases.

Dr. Lord then passed on to examine team work in its more practical aspects, and said that to establish or further develop team work in public mental hospitals would mean, in the first place, a reorganization of the work of the medical staff, and, in the second, an addition to it of specialists and experts in various other branches of medicine, and, where necessary, those of some special branches of clinical psychology. As little as possible of the time of the skilled psychiatrist should be spent on the chronic insane. Much more of the supervision and general care of this class of patient should be entrusted to nurses and skilled lay help. The house staff of a mental hospital should consist of psychiatric specialists and of

visiting or resident physicians. The ideal would be to utilize to the utmost the existing staff of medical officers and link them up with such specialists as the circumstances of each hospital required. At the head would be the clinical director, and each of the other medical officers should be required to make as might be necessary one or more branches of medicine besides clinical psychiatry a special study. The work should be done, so far as these special branches were concerned, under the direction of the appropriate visiting specialist, subject, of course, to the clinical director. Each hospital would settle for itself the number and character of its specialists and consultants, the most essential being a dentist, an ear, nose, and throat specialist, a neurologist, and a gynaecologist. The effort of the team should be first to concentrate on the ascertainment of the morbid physical processes at work and their alleviation, the psychic examination in the meantime being purely objective. In the final passages of his address he spoke of the reconstruction of psychiatry as a medical science, and pointed out what wealth of psychiatric material there was in general medicine. One field, the last to be cultivated, but perhaps the richest in potentialities, was the field of general practice.

#### *The Madness of Ajax Clinically Considered.*

Dr. G. A. AUDEN read a paper on the madness of Ajax as conceived by Sophocles. He said that the description of rapidly varying emotional states, with a maniacal outburst followed by depression culminating in suicide, furnished a clinical picture which must have been the result of experience. He compared it with the description of confusional insanity in a modern textbook. For accuracy in clinical detail Dr. Auden considered the Greek tragedian superior to Shakespeare, and claimed him as the first of the long line of physician-poets, extending down to our own day, as exemplified in the present laureate.

Dr. T. B. HYSLOP thought that the case of Ajax in a modern court of law would come under the M'Naghten rules, though whether the legal mind would properly assess it was doubtful. Sophocles was always interesting for his intimate knowledge of clinical psychology. Professor G. M. ROBERTSON said that the description of the symptoms of confusional insanity was about as perfect as it could be. If any student gave such a description as that given by Sophocles he would get full marks.

### BRITISH EMPIRE CANCER CAMPAIGN.

THE Duke of York presided at the third annual general meeting of the British Empire Cancer Campaign held in the House of Lords on July 12th, and drew attention to the activities of the various counties in establishing their own research centres or setting up county committees to aid the central fund. Sir John Ferguson announced that the midsummer ball organized by Lady Cave had yielded £1,600. To the annual report, edited by Mr. J. P. Lockhart-Mummery as in the previous year, Lord Cave, chairman of the Grand Council of the Campaign, contributed an introduction, in which he referred to the great impetus that has been given to cancer research, the harmonious co-operation which has been established between cancer research committees and individual workers, and to the publication of a journal of abstracts and reviews, for the initial expenses of which the Campaign has allocated funds. Grants for the year ending May 31st, 1926, were made to the Birmingham University Cancer Research Centre, £4,047; the Cancer Hospital, £2,500; Coombe Lying-in Hospital, Dublin, £200; the London Association of the Medical Women's Federation, £600; Middlesex Hospital, £3,000; St. Bartholomew's Hospital, £1,695; St. Mark's Hospital, £500; Westminster Hospital, £500. Grants had also been made to ten research workers, and £600 had been expended in connexion with visits to American and Continental cancer research laboratories; the total amount distributed was £16,757; the body of the report is taken up with statements from these institutions and individuals. The Cancer Research Department of the Middlesex Hospital has continued the investigations carried on last year, particular efforts being made to determine the way in which

the malignant cell differs from a normal cell. Experimental work has also been performed in connexion with tar cancer and the Rous sarcoma; in the latter case the work undertaken has been on the lines suggested by the researches of Dr. Gyo and Mr. Barnard. The effects of  $\alpha$  rays on metabolism have been further investigated, and researches continued into the Abderhalden reaction. Radiological studies included the general reactions of tissues to radium and  $\alpha$  rays, and the biological and chemical effects of visible and ultra-violet radiations. At the Cancer Hospital Research Institute various experiments with coal and acetylene tars have been made, and the work on the carcinogenic properties of mineral oils concluded. At St. Bartholomew's Hospital the effect of radiation on mitosis in the tumour cells is being investigated in the hope that some indication may be afforded thereby of the proper intervals which should be allowed in the split dose methods. At St. Mark's Hospital investigations are proceeding in connexion with the relation between simple and malignant tumours of the bowel; a survey is being made of the value of laboratory tests on the faeces in the diagnosis of cancer of the bowel, and investigations are being continued into the effect of large doses of colloidal copper and lead on malignant tumours. Under the auspices of the Campaign the old suggestion that "cancer houses" play an important part in the production of cancer is being studied. Professor R. T. Leiper now reports definitely that there is no evidence that the *Gongylonema* worm is associated with gastric carcinoma in man, nor that rats in old "cancer houses" harbour this worm and convey it to man. We referred on June 12th last (p. 1002) to this investigation of Professor Leiper, which has destroyed one of the few apparently solid pillars supporting the "cancer house" hypothesis.

### BEIT MEMORIAL FELLOWSHIPS.

THE annual report for the year ended June 30th, 1926, has been presented to the Beit Memorial Trustees by the honorary secretary, Sir James K. Fowler, M.D. It records that during the period under review research work has been carried on by two senior fellows, two fourth-year fellows, and twenty-two junior fellows. Dr. T. R. Elliott, F.R.S. (assistant honorary secretary), has now completed a record of the after-histories of all the Beit fellows appointed since 1910, and the details will appear in the next issue of the book of regulations.

#### *Election to Fellowships.*

The trustees have elected Ernest Basil Verney to a senior fellowship (value £600 per annum), and William Kershaw Slater, Harold John Channon, and John Maurice Hardman Campbell to fourth-year fellowships of the value of £400 per annum.

The following have been elected to junior fellowships, each of the value of £350 per annum.

RICHARD JAMES LYTGOE, M.A., B.Ch.Cantab., Sharpey Scholar, University College, London, who will investigate the electrical reactions of the optic and auditory nerves to sensory stimuli of varying wave-length, intensity, and quality.

FRANK MACFARLANE BURNET, M.D.Melb., temporary assistant, National Collection of Type Cultures, Lister Institute, who will undertake a study of bacteriophage in relation to the treatment of enteric bacillary infections.

JOHN GLOVER HUGO FREW, M.Sc.Birm., working at the Research Hospital, Cambridge, who will investigate the physiology of the blow-fly, particularly during metamorphosis.

MAURICE WALTER GOLDBLATT, M.D., B.Sc.Belfast, now working in the Dunn Laboratory, St. Thomas's Hospital, who will continue his investigation of (1) the relationship between ketosis and alkalosis; (2) the fate of the two terminal carbon atoms in the fatty acid chain during the hypothetical  $\beta$ -oxidation process; (3) the role of insulin in fat metabolism.

JAMES TUTIN IRVING, B.A.Cantab., Junior Demonstrator in the Sir William Dunn Institute of Biochemistry, Cambridge, who proposes to investigate in the Biochemical Department, Oxford, certain aspects of the metabolism of carbohydrates and allied compounds in the animal body.

JOHN GOWER STEPHENS, M.B., M.S., B.Sc.Sydney, now working in the Physiological Laboratory, Cambridge, who will continue his investigations of the functions of the spleen by the method of "window" observation.

BARNET WOOLF, B.A.Cantab., now working in the Sir William Dunn Institute of Biochemistry at Cambridge, who will undertake a comparison of some chemical reactions induced by resting bacteria with those induced by animal tissues.

## Scotland.

### NATIONAL HEALTH INSURANCE IN SCOTLAND.

At the annual meeting of the Scottish Conference of Friendly and Approved Societies held in Edinburgh on June 26th, Sir James Leishman of the Scottish Board of Health stated that the second valuation of the Scottish societies showed a gross surplus of over £4,000,000. There would, he said, probably be at least £2,500,000 available for distribution, which was two and a half times the amount available after the last valuation in 1918. He said that the year 1925 had been a fair year from the point of view of the health of the workers in Scotland, especially considering the long-continued depression in trade, the loss of contributions, and other adverse facts. He pointed out that representations had been received from societies regarding the present great number of claims, especially in certain areas. In connexion with some societies, the claims had increased recently by 50 to 100 per cent. above the claims usual at this time of year. He did not wish to go into the merits or demerits of industrial disputes, but he thought there was an intimate connexion with the general strike and the mining stoppage. Some societies said they were fairly sure that there was a large number of doubtful claims lodged for sickness and disablement benefit. The commission was sending out a circular to all medical practitioners calling attention to this alleged state of affairs and to the fact that the only good claim for sickness or disablement benefit was the claim of the person being unable to work. The great majority of societies probably looked with considerable confidence on the certificate of a medical practitioner as to a man's fitness for work, and he hoped that this would not be destroyed. Turning to the Royal Commission's report, Sir James Leishman said the chief recommendation was for an extended and fuller medical system. This should include all the specialist advice and treatment and all the institutional treatment necessary. The report by the committee on the hospital services of Scotland had shown a great deficiency in the accommodation and equipment of the voluntary hospitals. It was a serious matter that in the six large hospitals of the Scottish cities there had been no fewer than 5,864 people on the waiting list. He hoped that provision for the suffering would be practically the first charge on the generosity of all who could help. With regard to the distribution of the £2,500,000 it must be remembered that when spread over 1,700,000 people it came to only about 1½d. a week. He hoped that people would not get the idea that there was money to be given away to the first person who put out a big hand to get it.

### ST. ANDREWS ALUMNUS ASSOCIATION.

At a meeting of the General Council of the University of St. Andrews on June 26th Principal Irvine submitted the report of a committee appointed to consider the proposed establishment of an alumnus association in connexion with the university. It was decided to send a circular to all former students of the university inviting them to become members of the association, and to invite St. Andrews University associations throughout the country to become affiliated to the central association at St. Andrews.

### CHAIR OF NATURAL HISTORY AT DUNDEE.

At a meeting of the University Court of the University of St. Andrews on June 25th the vacant chair of natural history in University College, Dundee, was filled by the appointment of Mr. Alexander David Peacock, M.Sc. Dundelm., F.R.S.Ed., senior lecturer in zoology at Armstrong College, Newcastle-on-Tyne. Professor Peacock has done a large amount of research connected especially with entomology, and was previously entomologist in the Government Agricultural Department of Southern Nigeria. During military service from 1914 to 1919 he was engaged particularly in entomological research and instruction connected with the medical and sanitary services under the War Office.

### STANDARD OF INCAPACITY FOR WORK IN SCOTLAND.

The Scottish Board of Health has issued a circular to all insurance practitioners in Scotland relating to the certification of incapacity for work. The circular states that the Board had recently had occasion to consider the position arising from a sudden and very substantial increase in the certification of claims for sickness and disablement benefit, mainly in the industrial areas. So far as the Board had been able to discover, the apparent access of sickness indicated by the increased issue of certificates of incapacity for work was not attributable to any epidemic or outbreak of exceptional sickness. It appeared from the re-examination of a large number of cases by the district medical officers that the seeming increase was due to a less stringent view being taken by practitioners of the conditions for which sickness and disablement benefit was given, and the Board would impress upon insurance practitioners the fact that the statutory condition for payment of sickness or disablement benefit under the National Health Insurance Act is that the insured person shall be incapable of work through some specific disease or bodily or mental disablement. The Scottish Miners' Federation Approved Society has also issued a circular on the subject to their district agencies in which the situation is characterized as "an utter collapse from the normal standard of certification." It is also stated that the society's experience in 1926 corresponds to that in the industrial dispute in 1921.

### PURE MILK IN EDINBURGH.

A lecture on "A pure milk supply" was delivered by Dr. W. Robertson, medical officer of health for Edinburgh, in the Synod Hall, Edinburgh, on July 2nd. Preventive medicine would, he said, receive a strong impetus when milk free from disease-producing micro-organisms was generally available. Milk containing germs of tuberculosis was a menace to the very young and a risky food for the delicate. In course of time, he believed that those who had been strenuously advocating the production of tubercle-free milk would reap the reward of their efforts by witnessing the decline in the incidence of tuberculosis, more especially of bones, glands, and serous membranes. Powers now existed to deal with the diseased cow and were being employed by the Veterinary Department. By slow degrees the demand for tubercle-free milk in Edinburgh had increased until now several hundreds of gallons were sold daily. This meant that persons in the dairy trade were fast realizing the importance of a great problem, and it also proved that many consumers would pay an enhanced price for a reliable food. Those who had spent time and large sums of money in collecting tubercle-free herds must earn the gratitude of a public health authority. No longer did they stress such matters as ornamental byres, with tiled interiors and elaborate fittings; but, rather, importance was attached to clean cows, clean hands, and cleanly methods, with daily exercise for the animals. In another direction Edinburgh had led the way, and this was in the production of pasteurized milk, of which thousands of gallons were now being sold every week. Dr. Robertson believed that in the course of a year or so the dairies in the city would be selling little else than tubercle-free milk from tested cows, or milk that had been treated by pasteurization. During the past forty years there had been nine serious epidemics of scarlet fever in the city caused by infected milk, which had cost the city enormous sums of money. What was now required was a far more universal use of milk by young and old people. It was a valuable food and relatively cheaper than many other articles of diet.

### CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At a meeting of the Central Midwives Board for Scotland for the hearing of penal cases, Dr. James Haig Ferguson in the chair, it was reported that a certified midwife had been found guilty of procuring abortion and sentenced to penal servitude, and it was resolved that the secretary be directed to remove her name from the roll of midwives and to cancel her certificate, and in addition thereto, in terms of Section 8 of the Midwives (Scotland) Act, 1915, to prohibit

her from attending women in childbirth in any other capacity. Another certified midwife appeared in answer to charges of being guilty of negligence, breaches of the rules, and failure to notify to the local authority contact with a person suffering from puerperal fever, thereby endangering the lives of her other patients. Miss Jane C. Barker, assistant inspector of midwives, Glasgow, appeared in support of the charges. The Board found the charges to be proved, and resolved that, in view of the technical character of the offence, the midwife be severely censured and admonished to adhere strictly to the rules of the Board in future, and further, that a report be obtained from the local supervising authority on the conduct of her practice during the next three months. At the ordinary meeting of the Board held later, Sir Archibald Buchan-Hepburn, Bt., presented the report of the Finance Committee, which, on his motion, was approved.

## Ireland.

### COUNTY WEXFORD MEDICAL PRACTITIONERS.

At a meeting of the medical practitioners of County Wexford, at Enniscorthy, a report of the joint meeting of the medical practitioners of the counties of Wicklow and Wexford, which was held at Woodenbridge Hotel, Vale of Avoca, on June 17th, 1925, was read by the honorary secretary, and it was decided to stand by the resolution, as to the refusal to fill up the new Registration Quarterly Return Form, adopted at that meeting, and previously passed by the Irish Medical Committee on April 6th, 1925. A letter was read from Dr. Hennessy, Irish Medical Secretary, in which he gave an account of the proceedings in connexion with the meetings of the Committee of Inquiry into National Health Insurance and the Medical Services, of which Dr. R. J. Rowlette is a member, and of the Poor Law Commission, of which he (Dr. Hennessy) is a member. Dr. Hennessy also drew attention to the position of the funds out of which the remuneration for medical certification was paid, and urged that the County Wexford medical practitioners should take steps to organize to protect their interests in respect of medical certification, among other matters. The question of the organization of the profession in the Saorstát was considered, and the following resolution, proposed by Dr. Bowen, and seconded by Dr. Lawlor, was passed:

That in view of the many pressing and important questions that are likely to face the medical profession in Saorstát Eireann in the near future, we consider that the enrolment of all its members in one large association would add enormously to its strength and prestige, and we request the Irish Medical Committee to take such steps as it may deem necessary and expedient to have a scheme formulated which would amalgamate existing associations, rope in those who do not belong to any association, and give renewed life to medical politics in Ireland.

A communication was received from the County Wexford branch of the Irish Local Government Officials Union inquiring if it would be possible to effect an amalgamation between it and the Medical Association; after discussion, it was decided that it was not advisable to have a union of the two bodies on account of the varied interests involved; but in view of the possibility of the County Board of Health taking action towards the reduction of salaries it was agreed to ask the local branch of the Union to consult with the doctors in joint meeting.

## England and Wales.

### THE MILK SUPPLY.

THE Milk and Dairies Order, 1926, was issued by the Ministry of Health on July 12th. It revokes the Dairies, Cowsheds, and Milkshops Orders of 1885, 1886, and 1899, so far as they relate to England and Wales, and all Regulations made thereunder by local authorities. The main provisions of those Orders and Regulations are re-

placed by provisions similar in general purpose, but modified in accordance with the development of modern hygienic knowledge so as to lay greater stress on cleanliness in all operations connected with the production and handling of milk (including the care of the cow) than upon the structure of buildings. The most important of the new provisions are those relating to the health and inspection of cattle, and to the handling, conveyance, and distribution of milk. The Ministry has also issued Public Health (Imported Milk) Regulations, 1926. These require the registration by port and riparian sanitary authorities of persons receiving imported milk, and give power to the registering authorities, similar to that conferred by Section 2 of the Milk and Dairies (Amendment) Act, 1922, in regard to retailers, to refuse registration or to remove a person from the register if the requirements of the Regulations in regard to the condition of the milk are not complied with. These requirements—namely, freedom from tubercle bacilli and a limitation of the bacterial content—are, as the Minister is advised, such as can suitably be applied to milk which has been submitted to a pasteurizing or other heating process which is a commercial necessity for imported milk. The Milk and Dairies Order, 1926, will come into operation on October 1st next, and the Public Health (Imported Milk) Regulations, 1926, on January 1st, 1927.

### PRESENTATIONS TO DORSET DOCTORS.

On June 24th Dr. F. Rodier Heath of Weymouth and Dr. P. W. MacDonald of Radipole were each presented with a silver salver at a dinner held at the Town Hall, Dorchester, in connexion with the West Dorset Division of the British Medical Association and the Dorset Local Medical and Panel Committee. The chair was taken by Dr. E. Kaye Le Fleming of Wimborne, and Dr. G. C. Anderson, Deputy Medical Secretary, British Medical Association, represented the headquarters of the Association. Dr. MacDonald, who had been medical superintendent of the Dorset County Asylum, was in the past president of the Dorset and West Hants Branch of the British Medical Association and chairman of the West Dorset Division. Dr. O. Rees, chairman of the West Dorset Division, in proposing his health, referred to the active part Dr. MacDonald had taken in the difficult time at the commencement of the Insurance Act. As justice of the peace he had also served the county, and since his retirement he had devoted his energies to medico-political work. Dr. Le Fleming described the valuable service of Dr. Rodier Heath as secretary of the Panel Committee from 1918 to 1925; he had been particularly prominent in the task of overcoming difficulties between medical practitioners and the State authorities. The toast of "The British Medical Association" was proposed by Dr. T. MacCarthy, who gave several instances of the way in which the Association supported the interests of doctors which did not conflict with the larger interests of the general public. Dr. Anderson, in replying, referred to the Royal Commission into the national insurance system, and said he believed that the Association had persuaded the Ministry of Health to revert to the old transfer of practice system, with a month instead of a fortnight. He described also the recent scientific activities which had been fostered by the Association. The dinner was arranged by Dr. J. A. Pridham of Broadwey, who was highly complimented on its success.

### FURTHER MEMORIAL TO THE LATE DR. MARY STURGE.

Two wards in the Taylor Memorial Home of Rest in Birmingham have been set aside to the memory of Dr. Mary Sturge, who died on March 14th, 1925. These wards will be reserved for poor gentlewomen suffering from incurable malignant disease and unable to afford nursing home fees. It will be remembered that during her active life Dr. Sturge initiated the scheme for the erection of a nurses' home in this institution, which was opened on April 1st, 1925, and the Medical Women's Federation decided last year also to raise a fund to endow a bed in her name. A sum of £210 was collected by the Federa-

tion and presented, on July 2nd, at the annual meeting of the Taylor Memorial Home, by Miss Frances Ivens, president of the National Federation of Medical Women, and Dr. Lena Walker, president of the Birmingham and Midland Medical Women's Association. The annual report of the home showed that, during 1925, thirty-seven patients had been admitted, and twenty-three deaths had occurred in it. An anonymous donor had presented £1,000 for the endowment of a bed, and the Birmingham Hospital Saturday Fund Committee had given £100. The home has been placed on the list of institutions which share in the distribution of the Hospital Sunday Fund.

#### STRETFORD HOSPITAL.

A hospital for maternity cases was opened on July 10th at Stretford, near Manchester. Dr. T. Wheeler Hart, county director of the East Lancashire branch of the Red Cross Society, who presided over the ceremony, said that this, the first hospital to be erected in Stretford, was so particularly well equipped as to rival any of the kind in the country. Its building had been rendered possible through the generosity of Sir Thomas Robinson, M.P., who had advanced £2,000 free of interest, and by the East Lancashire Red Cross Society, which had provided another loan of £1,000. It was recognized that the ideal hospital provided accommodation for both men and women suffering from any illness, but such a complete scheme was not yet possible in Stretford. The trustees felt that the first consideration was the provision of accommodation for maternity cases, and they hoped to obtain later on an annexe for men. Sir Thomas Robinson explained that if an adequate response to the appeal was made by the inhabitants of Stretford the trustees would be able to proceed with the second section of the work. The annual upkeep of the hospital at present would require an income of £1,000 a year.

#### THE WARNEFORD HOSPITAL, OXFORD.

In commemoration of the centenary of the Warneford Mental Hospital, on Headington Hill, Oxford, the medical superintendent, Dr. Alexander W. Neill, has compiled a brief history of the institution. It appears that in 1813 the governors of the Radcliffe Infirmary, urged thereto by Dr. Cooke, president of Corpus, decided to establish an asylum for the reception and relief of insane patients. Weekly payments, according to their means, were to be made for the patients, who, preferably, should not be those who had received parish relief. Prolonged negotiations with the Oxfordshire magistrates prevented effect being given to these decisions until 1826, by which time £20,000 had been raised, and an asylum for thirty patients was erected on ten acres of land purchased at Headington. It was opened on July 10th, 1826, and was known as "The Oxford Lunatic Asylum." It supplied the needs of persons for whom the law provided no gratuitous assistance, but who had insufficient means for obtaining help. In 1828 the name of the institution was changed to "The Radcliffe Asylum," in recognition of the large contributions received from the Radcliffe trustees. Later on the Rev. Dr. S. W. Warneford, rector of Bourton-on-the-Hill, began to bestow gifts on the asylum, and in forty-two years his donations exceeded £70,000. In 1843 Dr. Warneford's gifts to and interest in the asylum had already become so great that as a permanent memorial the governors changed the name to "The Warneford Asylum." In 1849 Dr. Warneford obtained the grant of a Royal Charter. His friend the Rev. Vaughan Thomas helped in developing the charitable side of the institution, by means of which "a few poor curables of the county" could be admitted and maintained either gratuitously or at reduced prices. The hospital has been gradually developed and additional land has been purchased until the Warneford Asylum now accommodates 130 patients on an estate of 120 acres. The centenary was celebrated last Saturday by a garden party, which was attended by the president of the hospital (Lord Saye and Sele), the Mayor of Oxford, and many residents there, and many members of the University and of the medical profession.

## Correspondence.

### THE PROPHYLACTIC VALUE OF SCARLET FEVER ANTITOXIN.

SIR,—In a letter appearing on page 1011 of the JOURNAL of June 12th Dr. J. H. Garrett takes exception to the deductions in a paper with the above title which was contributed by two of my medical officers and myself to your issue of May 22nd.

In this paper an endeavour was made to give some indication to practitioners "in charge of children's institutions" as to the degree and duration of protection afforded to susceptible children by the use of prophylactic doses of scarlet fever antitoxin. The basis upon which susceptibility was assessed was a skin test dose of Dick toxin. There is abundant evidence to show that the Dick test is a reliable index of susceptibility or otherwise to the toxin produced by the *Streptococcus scarlatinae*.

The degree of infectivity of scarlet fever was not discussed in the paper. It is well known that scarlet fever is a disease of relatively low infectivity amongst the general population. It is also well known that patients suffering from diphtheria are peculiarly prone to contract scarlet fever, and vice versa. One reason for this is that children who are susceptible to diphtheria are commonly also susceptible to scarlet fever. The Dick-positive and Schick-positive curves in the earlier age groups of which such ward populations are chiefly composed run parallel.

During the last six years in one of the hospitals under my charge many hundreds of cases of scarlet fever have been nursed with safety in the same ward with other infective and non-infective diseases under the conditions of "bed isolation." Spread has only occurred on two occasions, both as the result of proved contravention of rules. But a diphtheria ward nursed on ordinary lines is a different matter.

In my opinion the production of passive immunity amongst non-immunes, even although this immunity is of limited duration, is a great advance on the old method of dealing with ward populations exposed to scarlet fever. This old method was practically based on the trust that the disease might not "extend to any considerable number of contacts or otherwise . . . show urgent need for control by an extraordinary method." Why take any risks with a ward population of susceptible children when a method exists by which these risks may be eliminated for an appreciable period?

Our paper dealt with institutional conditions. In the JOURNAL of January 30th appeared an apposite contribution from Dr. David Kirkhope bearing the same title as our paper. He, using a scarlet fever antitoxin prepared at the Lister Institute, inoculated 140 contacts (with 41 scarlatinal patients), and in addition 131 children "derived from school classes where scarlet fever cases were recurring with unhappy frequency. . . . From the time of the inoculations no further cases occurred in the school *for a fortnight and all the inoculated escaped infection.*" (Italics mine.) Dr. Kirkhope employed an earlier serum than either of those used by us. He found that the minimum protective dose of this serum was 5 c.cm., and that such a dose, he believed, protected for fourteen days. Dr. Kirkhope's estimates were based on the actual contraction of scarlet fever—after the lapse of the period of immunity—by contacts and exposed children (without reference to the Dick test). Some months, therefore, before our paper appeared he had arrived by a different route at substantially the same conclusion as ourselves.

But, after all, the production of temporary passive immunity, whether applied to the general population or to special populations under institutional conditions, although a great advance upon the "expectant" method, can only be regarded as an exceptional means of protection under certain conditions. The ideal is, of course, the production of lasting active immunity.

The production of active immunity against diphtheria is now a well established process, and through its agency diphtheria has, for example, been eliminated as a cause of

sickness amongst the nursing and domestic staffs of the Birmingham City Hospitals.

Active immunity against scarlet fever by means of multiple skin test doses of Dick toxin is also being produced by us, but sufficient time has not yet elapsed to speak with confidence as to its duration.—I am, etc.,

E. H. R. HARRIES,  
Medical Superintendent, Birmingham City Hospitals.

July 7th.

#### OBSTETRICS IN GENERAL PRACTICE.

SIR,—The distinguished author of *Operative Midwifery* deserves more consideration than would seem his due from the tone of some of his critics. While not agreeing with him in his suggestion that all serious midwifery work should be in the hands of specialists and removed from those of men in general practice, one sees that it is a reasonable proposition. It should be met, not with rudeness, but with that calm nonchalance with which, for instance, the sister proposition would be met by men of his position: the suggestion, namely, that as midwifery is essentially a woman's question, and as plenty of skilled women specialists would be available, the practice of midwifery should be carried on exclusively by women and that male teachers should be superseded. That in itself is also a reasonable proposition, and it would be pleasant to watch the calmness with which it would be received by the present teachers of obstetrics.

My own quarrel with Dr. Munro Kerr would be from another point of view. His title is alluring, and on reading his paper up to a certain point one's hopes were raised that here at last we were to have some light on the real point which, to my mind, is now at issue—the actual state of the woman herself, the changes brought about in pregnancy. Surely the day is come when we can no longer look on the pregnant as just an ordinary healthy woman who is going to have a baby. The biochemists and the workers on endocrine activity have altered that. She is fundamentally changed, and for the worse so far as her defences against disease in general and sepsis in particular are concerned. Such is the proper objective of Preventive Medicine as applied to Obstetrics, and Dr. Munro Kerr has advanced only a little way along the path towards it.

Another point I should wish to make. Everyone will agree that an obstetric operation should be dealt with as a major surgical operation. But, if so, it comes under the ordinary rules of surgery. Now one of the principal axioms in surgery is that, having made up your mind that operation is indicated, operate at once. My old chief Joseph Bell used always to say, "Get the patient off the table and into bed as quickly as possible," and the obstetrician should bear this in mind. If you work under strict antiseptic precautions your patient runs far more risk from delay and consequent exhaustion than from sepsis.

With regard to Dr. Munro Kerr's not original but interesting suggestion that another battalion should be added to the already bloated armaments of officialdom, may I suggest that the opinion of the "balancing elector," the poor woman herself, might be considered? She has her own doctor, who has brought all her children and perhaps herself into the world. Is it to be supposed for a moment that she would embrace with joy the idea of exchanging him for someone sent down from the nearest city by the medical officer of health? I should like to hear some of them on the point.—I am, etc.,

Cupar, Fife, June 30th.

C. E. DOUGLAS.

#### THE ROYAL MEDICAL BENEVOLENT FUND.

SIR,—I regret that absence on holiday has prevented an earlier reply to Sir Charters Symonds's letter (June 12th, p. 997). I am in complete accord with him as to the undesirability of provoking controversy on this matter; but I marvel that it has not occurred to him that the publication of such a letter, with its many debatable points, is the surest method of bringing about that which he desires to avoid.

My speech to which he takes exception was delivered nearly a year ago in an endeavour to persuade the Repre-

sentative Body to set up a separate British Medical Association Medical Benevolent Fund, which should have as its object the making of adequate provision for those of our profession and their dependants who had fallen on evil times—a task which the Royal Medical Benevolent Fund in its own annual report admitted it had failed, so far, to accomplish. The Representative Body in its wisdom decided against my policy, and instead set up a British Medical Association Charities Trust Fund Committee, whose duty it is to stimulate the profession to subscribe (through this committee) to existing medical benevolent funds, of which the Royal Medical Benevolent Fund is one of the most important.

As a loyal member of the British Medical Association I accepted that decision, and as a member of that Charities Trust Fund Committee and its first chairman I have used my best endeavours to carry out the wish of the Representative Body.

It is obvious, therefore, that to criticize (or even justify previous criticisms of) a fund for which it is the duty of my committee to appeal would create an impossible position which I could not attempt to justify.

I prefer, therefore, to bear any misconstruction which may be put upon my omission to reply in detail to Sir Charters Symonds's various points, rather than do anything to damp enthusiasm for an object in which I am very keenly interested.

I appeal earnestly to the profession to allow no word which I uttered in the totally different circumstances of July, 1925, to hinder them from most generously supporting the British Medical Association Charities Trust Fund, in order that our less fortunate brethren may be relieved from the distress and penury in which so many of them are at the present time involved.—I am, etc.,

JOHN F. WALKER,  
Southend-on-Sea, July 7th. Chairman, Charities Trust Committee.

#### FUNCTIONAL ALBUMINURIA IN ATHLETES.

SIR,—The following case should be of some interest to those of us who remember how much concern any form of albuminuria produced forty years ago. It was, as I then wrote, "the most marked case of functional albuminuria I have met with, one in whose urine I have often seen as much as one-half of the column in the test tube to consist of solid albumin. This is a case of a young gentleman, now aged 23, whom I have had under observation for six years, and who, though the albuminuria is as marked as ever, has fairly good health which has not deteriorated during that time." He had been a patient of the late Professor Sir Thomas Grainger Stewart of Edinburgh, who had kept him on a purely milk diet for thirteen months without in the least influencing the albuminuria.

The quotation is from a contribution made to the *Lancet* (December 10th, 1887). Its title was "Albuminuria in the apparently healthy." In it I reported the results of the examination of the urine of 461 persons. Of these, 369 were boys; of them 20.8 per cent. were albuminurics. By a series of tests I proved that the albuminuria was caused by rising from the reclining to the standing posture. I therefore called the condition "postural albuminuria." Sixty-four of the boys played wind instruments; of them 59.4 per cent. were albuminurics. This did not appear to controvert, but rather helped to substantiate, the theory then advanced that the temporary albuminuria was produced by a temporary paresis of the renal vessels.

The immediate point of interest is this: I hear occasionally from the "young gentleman" above mentioned. He is now 62 years of age and in good health. The albuminuria ceased entirely only a few years ago. Is this because the walls of the renal vessels had in the meantime changed their character?—I am, etc.,

ALEX. W. STIRLING, M.D.Ed.;  
D.P.H.Eng., F.A.C.S.

Atlanta, Ga., May 19th.

SIR,—I am encouraged to contribute some recent observations in relation to two athletic feats which for severity could hardly be surpassed.

In a successful attempt upon the world's record, G. C. walked a few yards short of 8½ miles in the hour. Urine

passed half an hour after the completion of the exercise showed a faint cloud of albumin, subsequently estimated at 0.1 per cent. (Aufrecht), very numerous oxalate crystals, hyaline and granular casts, but no blood. The urine passed six hours later exhibited a faint trace of albumin, very few granular casts, oxalate crystals, and no blood. That passed twelve hours later was free from albumin; oxalate crystals were still present.

The severity of the effort may to some extent be measured by the observation that G. C.—naturally in the best training—lost  $4\frac{1}{2}$  lb. during its performance. His temperature per rectum ten minutes after he had finished was 105.6° F. The shade temperature at the time was high (76°), but the air was dry and a light breeze encouraged free perspiration. The runner, a man of 42, an experienced athlete, who accompanied him throughout, lost 1 lb. in weight. No trace of albumin could be identified in any urine he subsequently passed.

It is worth noting that G. C., who is over 51 years of age, has a resting cardiac rate of only 41, and a maximum systolic blood pressure of 125 mm.

Mr. D. G. L., an Olympic champion, aged 23 $\frac{1}{2}$ , in the course of the greatest effort of his distinguished career ran half a mile inside world's record time. The urine he passed four hours afterward—the first available—contained an almost imperceptible trace of albumin. This albumin "was precipitated in the cold by the addition of dilute acetic acid and had the characters of the orthostatic albumin of adolescent urines." Microscopy of the centrifugized deposit contained oxalate crystals, but no casts or blood.

It is at least an interesting coincidence that oxalate crystals were present in all the specimens examined. In the case of Mr. L. no opportunity was afforded for further investigation; in G. C.'s case oxalates were found twenty-two hours after the exercise. No dietetic peculiarities could be correlated with their occurrence, but if, as is sometimes urged, oxaluria is dependent upon some nervous association, there was certainly abundant provocation in both instances.

I acknowledge most gratefully my indebtedness to Mr. Herbert Perkins, pathologist to the Hampstead General and Children's Hospitals, for the interest he took in the proceedings, and the time and trouble he generously devoted to the investigation.—I am, etc.,

London, W.1, July 10th.

ADOLPHE ABRAHAM.

#### "ATOPHAN DERIVATIVES IN RHEUMATISM."

SIR,—Dr. Langdon Brown and Dr. Geoffrey Evans have issued a timely warning about the use of atophan and its derivatives. I can illustrate their letters by the following case.

An elderly lady went to Germany for treatment for rheumatism. While there she was given five intravenous injections of 5 c.cm. of Messrs. Schering's atophanyl, only one or two days being allowed between the injections. On her return she produced a box containing five ampoules of atophanyl, which she had been directed to ask me to administer. Being somewhat fearful of intravenous medication, and also seeing that her anatomy was not kindly disposed towards that line of drug administration, I proceeded cautiously. I gave doses of 2 c.cm., then 3, 4, and 4.5 c.cm.—four injections at intervals of about four days. After the last one she complained of indigestion, and within another five days jaundice set in. This is now a month ago, and it is only during the last few days that we can say she is really beginning to improve. Dr. Canti and Dr. Archer kindly investigated the blood and the evacuations for me, and they reported that "the jaundice is of the so-called haemolytic type." The colour in this case interested me, as it was more of a deep chrome yellow than the usual greenish yellow of catarrhal jaundice; also the pulse remained about 68 to 80, and did not drop down into the 40's and 50's, as is so often the case in the latter disease.

I understand that these incidents occur after atophan taken by the mouth, as well as—as in my case—after atophanyl given intravenously. One must suppose that there is some factor at work in the patients who get jaundice that is not present in those who escape it; I cannot offer any suggestion on this matter. I am assured by

the professor who ordered these injections that jaundice after their administration is unknown in Germany. Nevertheless it is wise that a word of warning should be given regarding the use of these drugs, and doubtless we shall hear some more facts hereafter concerning them.—I am, etc.,

Hampstead, July 10th.

LEWIS G. GLOVER.

SIR,—I was rather surprised to read Dr. Langdon Brown's letter in your issue of July 3rd, recording two fatal cases following the use of atoquinol.

I have records of thirty-three cases in which I have prescribed atoquinol, both by mouth and as an ointment, without a single sign of toxicity. One case of very severe rheumatoid arthritis persisted with the treatment, taking four tablets daily with night and morning inunction for six and a half months without any satisfactory result, though the pains were undoubtedly relieved, but also without any toxicity.

I have always insisted on the simultaneous taking of sodium bicarbonate 5 grains for every tablet of atoquinol, and on a minimum of two quarts of fluid daily.—I am, etc.,

London, W.1, July 9th.

L. C. DUNDAS IRVINE.

#### RECOVERY AFTER MASSAGE OF THE HEART.

SIR,—It is of the utmost importance in every case of recovery of the heart's action, that the means adopted should be most accurately recorded: this must be my excuse for troubling you again on this subject.

Mr. Spackman's case (BRITISH MEDICAL JOURNAL, July 3rd, 1926) is very interesting as indicating adrenaline as the efficient cause. But hearts have a way of stopping and restarting *sua sponte*, as it seems; we are all familiar in the physiological laboratory with Luciani's phases. Therefore we want to know exactly, not only the dose of the remedy, but that it reaches its destination—namely, the cavity of the right heart. Mr. Spackman injected 10 minims of the 1 per 1,000 of adrenaline into "the apex of the heart through the fourth space." This is not precise enough; it should be, according to Dr. Bodon, the "fourth left interspace, at the upper rim of the fifth rib close to the sternal border"; the needle should be 8 cm. in length (just over 3 inches), and it should be carried from front to back with a slight inward direction—that is, towards the mid-line. Should any other site be elected for special reasons, it and any other modification of procedure should be precisely reported. In children and adults of small build, the whole length of the needle would not be required to reach the heart's cavity.—I am, etc.,

London, W.1, July 9th.

HARRINGTON SAINSBURY.

#### OPHTHALMIC EXAMINATION IN INFANCY.

SIR,—There is one cause of error of refraction that is at once remediable, if I am right in suspecting foreal damage from the exposure of infants to sky glare in the dorsal position in the open perambulator. Damage to the macula in this way is conceivable in view of the frequency of eclipse blindness, and might well account for some problematic cases of poor visual acuity in normal eyes; indeed, in abnormal eyes also, since such errors as astigmatism, myopia, presbyopia, etc., could be brought about secondarily thereto. It is a well known fact that interference with the macula by corneal opacities within the first seven months gives rise to nystagmus.—I am, etc.,

London, W.1, July 12th.

HORATIO MATTHEWS, M.D.

#### RADIOGRAPHY OF MAXILLARY ANTRUM.

SIR,—Dr. McKelvie in his article on the radiography of the maxillary antrum (July 10th, p. 58) recommends the use of lipiodol as an opaque medium to demonstrate the filling defect in an antrum in which either malignant disease or polypi are present.

I have on many occasions used the same method, employing bismuth in paraffin with a small amount of iodoform; this gives a good shadow and is very much cheaper than lipiodol; moreover, it is necessary to plug the nose, for the bismuth-paraffin solution remains in the antrum for a sufficient time in all cases to allow a ski-

gram to be taken, while in certain forms of sinusitis it remains in the antrum for several days.

I can certainly endorse Dr. McKelvie's opinion that the method is of value.—I am, etc.,

Birmingham, July 12th.

A. LOWNDES YATES.

### COAL AND HYGIENE.

SIR,—At first sight the relationship between medicine and coal may not be very apparent, but looked at more closely the study of coal and its constituents becomes interesting, especially from the point of view of preventive medicine. An average sample of British bituminous coal yields by carbonization 7.5 per cent. of tar, 2½ gallons of refined benzol per ton, about 3,500 cubic feet per ton of a rich gas having a calorific value of 800 British thermal units, and a 75 per cent. residue of a superior form of coke.

In the near future the tar, benzol, and gas will be first extracted from the raw coal, and the residue, which is a form of coke, produced by the low-temperature carbonization process, very superior in quality to the ordinary gas coke now supplied, will be used for heating purposes, domestic fires, etc. As a result the pollution of the air of our great cities by smoke, tar, ammonia, etc., will almost cease, and the health and well-being of the inhabitants will be greatly improved. It behoves all medical men, but more particularly medical officers of health, to urge upon local authorities the adoption of means to bring about this desired result. Incidentally, it may be stated that the value of coal is much increased when the raw coal is treated as stated above.—I am, etc.,

Sheffield, June 25th.

E. B. HAZLETON, M.D., M.Ch.

### ST. KILDA.

SIR,—Your leader on St. Kilda to me is most interesting, as I visited the island in 1886, and on the run out picked up two women who had been on the mainland for their confinements; from them I obtained information. The cause of the infantile mortality was doubtful. Some considered it was the irritation of the fulmar oil; but these women and others considered it was due to a local ointment applied to the navel cord. I obtained some fulmar oil, and used it at home on the navels of kittens, puppies, and rabbits, with negative results. I was unable to get any of the local ointment—it seemed a secret; but as I learned that the children died from sloughing round the cord area I considered that the ointment might contain arsenic; but I never had any opportunity of ascertaining whether there was any arsenic in the soil.

They were a sturdy people, the men idle, the women doing nearly all the work. A medical man had not been there for some years; nearly all the young women wished to get to the mainland. We brought back a man with malignant rectal trouble; he died in Glasgow.

They make a most wonderful cloth in St. Kilda. I bought some for a shooting suit, and it lasted for years, but smelt of fulmar. They possess a pack of dogs which scratch out the birds' eggs, and have sheep with four horns, from which they pluck the wool instead of shearing. This collecting of the wool seems an annual rite or feast; the elders take the maidens from isle to isle. There was great religious dissatisfaction caused by the minister, who spun out the services to some eight hours each Sunday; he seemed ruled by his housekeeper. The chapel bell was an old Armada one.—I am, etc.,

Folkestone, July 12th.

P. BROOME GILES.

### The Services.

#### INDIAN MEDICAL SERVICE.

THE revised terms and conditions of service of medical officers in the Royal Navy, Royal Air Force, and Royal Army Medical Corps, issued in accordance with recommendations of the Inter-departmental Committee on the Medical Branches of the Fighting Services, were published in our issue of July 3rd (p. 41).

Revised regulations for the appointment of candidates to commissions in the Indian Medical Service have now been issued by the India Office, together with a separate notice

on the subject of special recruitment. As reorganization of the medical services in India is now under consideration, candidates are notified that these regulations are subject to amendment accordingly.

The notice headed "Special Recruitment 1926" appears to differ little from the advertisement by the India Office which appeared in the advertising pages of the *BRITISH MEDICAL JOURNAL* in March, 1925, except in regard to overseas allowances and gratuities. An increase of 50 rupees per mensem in the overseas allowance has been granted to all officers after six years' service, except in the case of captains in their twelfth year of service, who receive an increase of 100 rupees per mensem. As regards gratuities, £1,000 will now be given after six instead of five years' service as heretofore, and there is a new provision for a gratuity of £2,500 after twelve years' service.

#### NORTH PERSIAN FORCES MEMORIAL MEDAL.

THE War Office announces that Dr. W. Corner, O.B.E., Iraq Health Service, has been awarded the North Persian Forces Memorial Medal for the year 1925, for his paper "Malaria in the Kirkuk Division of Northern Mesopotamia during 1923," published in the *Transactions of the Royal Society of Tropical Medicine and Hygiene*, 1925, vol. 19, Nos. 1 and 2, pp. 41-69.

This is the third award of the medal, which, in accordance with the terms of the trust deed of the memorial fund, is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding twelve months by any medical officer of under twelve years' service, of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or of the Colonial Medical Service, provided the memorial committee considers that any of the papers published has attained a standard of merit justifying an award.

## Universities and Colleges.

### UNIVERSITY OF OXFORD.

THE following candidates have been approved at the examinations indicated:

FINAL B.M., B.Ch.—C. P. Blacker, J. C. K. Ch'leath, A. V. Clenauer, G. H. Crisp, O. R. Croft, H. E. Cuthbert, J. N. C. Ford, E. L. Fothergill, E. A. Hamilton, W. H. Hasson, T. C. Hunt, J. H. Kennedy, D. Laurie, P. Morton, D. I. Rees, F. J. Sale, J. de la M. Savace, T. H. Sellors, R. W. A. Simmons, G. P. Thorold, O. B. Tisdall, W. R. Wood, Margaret N. Jackson, Constance I. Pattullo, Rosa S. Wordsworth. (*Forensic Medicine and Hygiene*): H. W. Allen, C. Charleson, P. F. Cluver, G. H. Crisp, H. E. Cuthbert, W. N. Dickenson, C. L. Harding, R. C. Hodges, W. H. Hudson, J. H. Kennedy, P. Morton, R. Oddie, J. S. Rake, I. H. Lister. (*Pathology*): H. E. Cuthbert, J. A. Eddy.

Joyce Wright.

### UNIVERSITY OF LONDON.

#### The Bloomsbury Site.

THE Senate on June 23rd authorized the Co-ordination and Developments Committee to approach the Duke of Bedford to ascertain whether and on what terms he would be prepared to negotiate the sale or lease of the land in Malet Street now occupied by the University, or of other land for the institutions connected with the University now on the Bloomsbury site.

#### Committees.

Sir Holburt Waring, M.S., F.R.C.S., has been appointed chairman of the Finance Committee, and Sir Wilmot Herringham, K.C.M.G., M.D., chairman of the Committee of Members of the Senate.

#### Brown Animal Sanatory Institution.

The annual report of the Superintendent of the Brown Animal Sanatory Institution for 1925 records that the number of animals brought to the institution during the year was 3,637. The five lectures required to be given under the will of the late Mr. Brown were delivered by the Superintendent at the Royal College of Surgeons of England in December, 1925, and dealt with the physiological and pathological activities and functions of bacteria. Experiments by several workers of other institutions had been carried out in the laboratories on subjects including human, bovine, and avian tubercle bacilli and gall-stone experiments. The Superintendent had continued his work on the ultramicroscopic virus for the Medical Research Council. He had also worked on the transmissible bacterial lysis and had come to the conclusion that the lysis might act on dead bacteria if living ones of the same variety were present. The report states that Dr. Gratia of the Pasteur Institute, Brussels, having carried out similar experiments, believed that the dead bacteria were autolysed by the living ones, but the result of experiments at the institution did not support the view that autolysis were entirely the cause of the dead bacteria being dissolved. Investigations in several other

**Lecturers.**

The following were elected to give lectures during the ensuing year:

**Hunterian Professors.**—Sir Arthur Keith: Six lectures on recent researches carried out in the Museum. Vincent Zachary Cope: One lecture on shock and collapse in acute abdominal disease. James Ernest Helma Roberts: One lecture on the diagnosis and treatment of intrathoracic tumours. Ernest Marshall Cowell, D.S.O.: One lecture on recent advances in the surgery of hernia. Arthur Hughes Southam: One lecture on the pathology and treatment of the retained testes in childhood. Bernard Warren Williams: One lecture on the importance of toxæmia due to mærobic organisms in intestinal obstruction and peritonitis. John Howell Evans: One lecture on testicular tumours of congenital origin.

**Arris and Gale Lecturers.**—Ralph St. Leger Brockman: One lecture on the cause of toxæmia and death in acute obstruction. Hildred Carlill: One lecture on the simulation of surgical affections by hysteria. Alfred Piney: One lecture on hyperplasia and neoplasia in lymphatic tissue.

**Erasmus Wilson Lectureship.**—Clement Edward Shattock: Six demonstrations on pathology.

**Arnott Demonstratorship.**—Sir Arthur Keith: Six demonstrations on the contents of the Museum.

**Lister Medal.**

At a meeting of the Lister Medal Committee on June 3rd last the Lister medal for distinguished contributions to surgical science, with the honorarium of £500, was awarded to Professor A. F. von Eiselsberg of Vienna. In compliance with the conditions of the trust, Professor von Eiselsberg will give an address at the Royal College of Surgeons at some date in 1927 convenient to the President and Council.

**The Museum.**

It was decided that the Museum be closed during August as well as during September, and for such part of July as may be found necessary in order to facilitate repairs and redecoration.

Diplomas were granted jointly with the Royal College of Physicians to 6 candidates in psychological medicine and to 11 candidates in laryngology and otology. Licences in dental surgery were granted to 68 candidates.

**Primary Fellowship Examination.**

A report from the Board of Examiners in Anatomy for the Fellowship was read, stating that at the examination concluded on June 17th, 129 candidates were examined, of whom the following 42 were approved and 87 rejected:

F. G. All.  
Black.  
R. A.  
H. N.  
S. I.  
R. J.  
J. H.  
Walker, H. S. Waters, N. L. White, P. Wiles, Beatrice M. Willmott, Margaret D. Wright, S. Zuckerman.

**Medical Notes in Parliament.**

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons this week debated Estimates for the Ministry of Health, Ministry of Transport, and the Post Office, discussed a motion relating to the business interests of Ministers, and further considered the Finance Bill on Report. The discussion on the Ministry of Health Vote was marked by a general concentration on health subjects, such as has previously been lacking in discussions about this department. The report of the Select Committee on Nursing Homes was due for publication during the week, but had not been issued at the time we went to press.

**The Ministry of Health Vote.**

In the House of Commons, on July 13th, the vote for the salaries of the Ministry of Health was discussed.

Mr. Neville Chamberlain (Minister of Health) said that cancer was increasing at an alarming rate. Last year, in this country, 1,336 deaths from cancer occurred per million, which was equivalent to the death of 50,000 persons. It had been estimated that out of every seven persons in this country who reached the age of 30 one would die of cancer. It was important that the public should be educated so that the disease could be treated in its early stages. The significance of the discovery of Dr. Gye and Mr. Barnard was that cancer was due to a virus which entered the body from outside, but which did not produce cancer until and unless it was associated in the body with some other factor, the nature of which had not yet been clearly ascertained.

The right hon. gentleman proceeded to direct the attention of local authorities to the experiment which was being carried out at Papworth by Dr. Varrier-Jones in regard to the treatment of tuberculosis. There was here an opportunity for a big progressive local authority to start a settlement of its own on Papworth lines.

Small-pox was rapidly increasing in this country. The number of cases were as follows: In 1922, 973; 1923, 2,500; 1924, 3,800; 1925, 5,300; and in the first six months of this year, 5,500 cases.

This increase must be regarded without a great deal of anxiety. It was true that the disease was occurring in a very mild form, but in the past this mild form had coexisted with a deadly form. If this were to reappear, those who fulminated against vaccination would rush to the vaccination officer. Vaccination against small-pox was regarded with prejudice by a large number of people; the vaccination laws were framed a good many years ago, and knowledge had increased and widened since then. At present there were seventy different diseases for which vaccination was practised to secure immunity. Small-pox was the only instance in regard to which compulsion was applied. It might be that the very fact that this particular disease was picked out and separated from the others for this exceptional legislative treatment had served to inflame the fanatical feelings against it, which had led to so large a proportion of our population going without vaccination. At any rate, he had recently set up a committee, under the chairmanship of Sir Humphry Rolleston, to investigate the whole subject, and he was content for the present to await the report and any recommendations which it might make on the subject.

A good deal of alarm had been created by the very distressing after-effects of lethargic encephalitis. It was unfortunate that as matters stood at present there was considerable difficulty in providing proper treatment. The legal definition of mental deficiency would not cover such cases; certification for lunacy was inappropriate. That was engaging his very serious attention, and it might be that he would have proposals to make to Parliament before very long to meet it. It was reassuring to know that the disease appeared to be on the wane. The number of cases, which had been 5,039 in 1924, came down to 2,635 in 1925. It was justifiable to draw the conclusion that this complaint, which appeared so suddenly and developed so rapidly, had reached its maximum and was now passing away, and that soon it would become, not a matter which could be neglected indeed, but one which would no longer give serious concern and anxiety.

Sir M. Macnaghten referred to a letter from the Ministry of Health to the Edmonton District Council, which, he said, placed an absolute prohibition on a doctor in a maternity centre giving advice or information to a woman on the subject of birth control. The letter stated that while a doctor could not give the advice himself, he might refer the woman for advice to a private practitioner or to a hospital. In default of compliance with the instruction, the grant would be withdrawn. Obviously, he said, maternity centres ought not to be converted into birth control clinics, but all that was asked was that in the case of a poor woman a doctor should be in a position to give this advice and information.

Dr. Fremantle said that statements had been published with regard to the starvation of the children of the miners, but he had seen no evidence in support of those assertions. On the other hand, evidence from medical clinics and welfare centres went to show that the health of the children was better now than before the strike. Dealing with the question of deaths in childbirth, Dr. Fremantle said that the report on public health for 1924 contained very serious figures, showing how unprogressive had been the treatment of that question. Although there had been a considerable reduction in maternal mortality, it had not been in proportion to the reduction in infantile mortality. There had, indeed, been an actual increase in the mortality of mothers in childbirth. There was great room for an increase in the number of beds in maternity homes, especially in view of the lack of proper accommodation in working-class homes. Maternity homes should be regarded, not as permanent institutions, but as makeshifts, until proper accommodation for maternity cases was provided in all homes. Another question of great importance was the supply of clean milk. Again, there was no provision for the supervision of health in coal mines. They heard of certain diseases among the men which were exceedingly troublesome. The Ministry of Health ought to take up the attitude, more and more, of being responsible for the health of the people in every department, and of knowing what health conditions were all over the country.

Dr. Vernon Davies said that it was true that for the last fifty years there had been a very happy and steady decrease in tuberculosis, except in the war years 1913 to 1918, when for temporary reasons there was an increase. But, despite that decrease, consumption still took a terrible toll of the younger people. He proceeded to review the machinery which existed at the Ministry of Health for dealing with the disease, and paid a tribute to the work of the panel doctor, who was the first link in the system of treatment. The Ministry had added to the panel doctor tuberculosis officers, who were expert in the diagnosis and treatment of consumption. To get the full benefit of sanatorium treatment the cases must be taken early. The great want was for village settlements, and the Minister of Health ought to give a lead in this matter. The Ministry should divide cases of tuberculosis into two groups—those that could be cured and those which were too far advanced. Sanatoriums should be kept absolutely for the curable cases, and the unfortunate people who could not be cured should be removed from their homes to the Poor Law hospitals. His visit to M. Spahlinger had convinced him that he had made out a *prima-facie* case for his treatment. M. Spahlinger was a wonderfully clever scientist and was working on strictly scientific lines, without the slightest desire for money. But a difficulty was found in tying him down to any definite legal agreement. Now he had no money at all, having spent £60,000 in his experiments for the good of humanity, and he was living from hand to mouth by taking odd patients who gave a subscription or donation to his institution. The one essential thing for M. Spahlinger was to be able to produce his serum and enlarge his laboratory and stock. He (Dr. Davies) appealed to the Minister of Health to vote a certain sum, say £50,000 or £100,000, to M. Spahlinger for the purposes of his research work.

The University of London Bill was considered by the House of Lords on July 9th. On Clause 7 (provision for the incorporation of colleges and schools) Earl Beauchamp proposed that no statute made under the bill should provide that no statute made under the bill, except with the assent of the House of Commons, should provide for the incorporation of any institution existing on January 1st, 1825, except with the assent of the House of Commons. The Earl of Balfour (Lord of the Council), who is in charge of the bill, said that

ing for  
ump moved a  
d affect any  
n the consent  
President of  
at he did not

*The General Medical Council.*—Mr. Erskine, on July 8th, asked Major Hennessy, as representative of the Lord President of the Council, what was the object in appointing a lay member of the General Medical Council. Major Hennessy said it would be contrary to practice to disclose the grounds on which the Privy Council advised the King to make the appointment. Mr. Erskine was doubtless acquainted with the public discussion on the constitution of the General Medical Council. Sir N. Gratton Doyle asked whether the appointment of a lay member signified any

range in the policy which the General Medical Council had adopted towards Dr. Axham. Major Honnessy asked for notice of that question. Mr. Erskine asked if Dr. Collis, a registered medical practitioner, was now acting in the same capacity as Dr. Axham had acted in times gone by to Sir Herbert Barker. The Speaker asked to see the question in writing, as it appeared to involve an individual. Mr. Macquisten asked if the purpose of appointing a lay member to the General Medical Council was to abate the autocracy of the medical profession and to dilute its fanatical trade unionism. The Speaker suggested that Mr. Macquisten should abate some of the adjectives in his supplementary questions.

**Recognition of Manipulative Practitioners.**—Mr. Chamberlain, being asked on July 9th whether he would consider the institution of an inquiry into manipulative surgery with a view to the recognition and registration of manipulative practitioners, said he would not. He had nothing to add to the statement he made in the debate on February 9th, which arose on a motion by Mr. Graham Little. The question had then been fully discussed.

**General Disease in the Royal Air Force.**—In an answer to Mr. Vernon Davies, on July 7th, Sir Samuel Hoare said the incidence of primary syphilis and gonorrhoea in the Royal Air Force at home and abroad during the last three years for which figures are available was (per 1,000 sick daily)—Syphilis: 1922, .36; 1923, .040; 1924, .031. Gonorrhoea: 1922, 2.29; 1923, 2.17; 1924, 2.0. There was no reliable information as to the proportion of cases in which preventive measures were used.

**M.O.H. and D.P.H.**—In a reply to Mr. R. Young, Mr. Chamberlain said he had informed the council of Golborne, Lancs., that the candidate selected by it as medical officer of health did not possess the requisite qualifications he was not at present prepared to give a sanction which would enable the council to obtain repayment from the county fund of one-half of the salary of the officer.

**Research Institutions in the Dominions, Colonies, and certain Foreign Countries.**—On July 12th Mr. Ormsby-Gore told Mr. J. Williams that arrangements had been made by the Department of Scientific and Industrial Research for communicating regularly published and other information as to the work done under its auspices to Dominion Government research organizations and to the principal unofficial research centres. Similar communications were sent to the Governments of India and the colonies. In return, valuable information was received by the department from the overseas parts of the Empire. Mr. Williams asked whether there was any interchange of opinion with the Dutch and French colonies. Mr. Ormsby-Gore replied that there was no direct interchange, but practically all Colonial Office research officers got reports from places like Guiana and Java, and the work of the French in this matter was followed in the appropriate institutions of research in this country. Dr. Haden Guest asked if the research institutions of the British Empire were in touch with the international research institute in Italy. Mr. Ormsby-Gore: Yes. Dr. Haden Guest asked if it would be possible to have a Government publication, setting out the present conditions of all these different research institutions. Mr. Ormsby-Gore replied that he had gone into the matter recently. There was a suggestion that, by co-operation with the Imperial Institute, more regular publication might be obtained of the names of research officers in different parts of the Empire and the main subject with which they were dealing. That was not yet decided.

**Illness in Officers' Training Corps.**—On July 12th Sir L. Worthington-Evans (Minister of War) told Mr. Rennie Smith that there were no records in the possession of the War Office from which he could give an analysis of the infectious illness of 3,660 members of the junior division of the Officers' Training Corps who were for this reason prevented from attending camp in 1925. It would be erroneous to assume that the 3,660 members in question were ill. The great majority were "contacts" who were not allowed to attend camp owing to the risk of spreading infection.

**Control of Nursing Association Homes.**—On July 12th Mr. Penny asked the Minister of Health whether, in view of the inability of nursing association committees to deal with the technical side of their activities, he would introduce legislation enforcing the composition of an advisory committee of local medical men in all cases in addition to the regulations for inspection now in force. Sir K. Wood replied: It is clearly desirable that a nursing association which undertakes the management of an institution such as a maternity home should have the benefit of medical advice, but the Minister doubted whether it would be expedient to attempt to enforce, by legislation, such a condition as was suggested. Mr. Penny asked whether any alternative way of doing this would be considered. As these institutions were to a very large extent local institutions would it not be better if local medical men inspected them periodically? Sir K. Wood replied that the Minister of Health had already made various suggestions with regard to this particular case, with a view to improvement, and if Mr. Penny had any suggestion to make he would consider it.

**Regulations for Bakchouses.**—The Home Secretary told Colonel Day, on July 8th, that proposals requiring the adoption at bakchouses of certain special precautionary measures against dermatitis had been communicated to associations representing employers and employed, and the views of these associations had been considered. He had decided to proceed at once with the issue of an Order

for the baking industry under Section 7 of the Police, Factories, etc. (Miscellaneous Provisions), Act, 1916. Any objections lodged would have to be considered before the Order could be finally made.

#### Notes in Brief.

On July 12th the Bethlehem Hospital Bill was read the third time in the House of Commons.

On July 8th Mr. Churchill said no final decision had been reached about the provision by the Treasury of accommodation for the headquarters of London University.

On July 13th the Reading University Bill was read the third time in the House of Commons.

## Obituary.

### SIR JOHN SHERBURN, M.B., C.M.,

Consulting Surgeon, Hull Royal Infirmary.

WE regret to record the death of Sir John Sherburn, on July 7th, at the age of 75, after a long period of ill-health. He received his medical education at Edinburgh, where he graduated M.B., C.M. in 1875; two years later he obtained the diploma M.R.C.S.Eng. He was closely associated with the Hull Royal Infirmary, where he had held the posts of house-surgeon, pathologist, and honorary consulting surgeon. He was also connected with the founding of the Hull Victoria Hospital for Sick Children, to which he was honorary consulting surgeon.

In addition to his extensive medical practice in Hull, Sir John Sherburn was a partner in the shipping firm of Bailey and Leatham; and took a prominent part in the public life of the city; he was elected sheriff in November, 1886; in the following year he became mayor, and held the office for two years in succession. In 1889 he was appointed justice of the peace for Hull, and later for the East Riding of Yorkshire. For twenty-three years he was connected with the East Riding Artillery Volunteers, and after his retirement he retained his rank of lieutenant-colonel. On three occasions he was a candidate for Parliament in the Liberal Unionist interest, but was defeated. He was created a knight in 1902. He leaves a widow, two sons, and three daughters.

### NEIL MACLAY, M.B., C.M.,

Surgeon, Throat, Nose, and Ear Hospital, Newcastle.

DR. NEIL MACLAY of Newcastle-on-Tyne died with tragic suddenness on June 26th, at the age of 53, while on holiday at Bamburgh. A student at Glasgow University, he graduated M.B., C.M. in 1895. After gaining experience in several assistantships in various places he commenced general practice at Wallsend-on-Tyne in 1899. While carrying on an extensive practice he found time to interest himself in diseases of the nose and throat, and became honorary surgeon to the Throat, Nose and Ear Hospital, Newcastle-on-Tyne. In 1911 he determined to devote all his time to that special branch of work, and for that purpose removed to Newcastle-on-Tyne. At the time of his death he was senior surgeon to the Throat, Nose and Ear Hospital and aural surgeon to the Infectious Diseases Hospital, while carrying on a very busy practice. A Fellow of the Royal Society of Medicine, and a member of the Scottish Otological and Laryngological Society, he was a frequent and enthusiastic attendant at meetings in London and Scotland. Indeed, on the day he died he had intended travelling to Edinburgh for a meeting of the latter society. At the time of his death he was president of the Newcastle-on-Tyne and Northern Counties Medical Society, of which he had previously been secretary. He was vice-president of the Section of Laryngology, Otology, and Rhinology at the Annual Meeting of the Association at Bath. Apart from his duties as surgeon to the Throat, Nose and Ear Hospital he found time to interest himself largely in its administration and particularly in its recent extension. During the war he was very actively engaged in the formation of the Tyneside Scottish battalions, and acted as medical officer for a considerable time.

He contributed numerous articles to the *Journal of Laryngology on diseases on the sinuses and related subjects.*

A man of stolid and dogged perseverance which he practiced or recreation; he manifested also great personal sympathy with those whom he attended professionally. His work was always quietly performed, and he seldom came into public prominence. During the later years of the war he was laid aside for many months with illness, borne with fortitude and patience; this occurred at a critical time in his career as a specialist. He has died in the heyday of active and prosperous practice at an early age. To say that he will be missed is merely banal; the profession is the poorer for the loss of such a man. For those who were privileged to know him intimately there is a gap which cannot be filled, the loss of a friend of ripe experience and knowledge of the world who was always ready to help and advise. He leaves a widow and one son, who is studying medicine. G. H.

Lieut.-Colonel WILLIAM HOTSON CADGE, I.M.S. (ret.), died at Lowestoft on July 9th, where he had lived since the end of the great war. He was the second son of Mr. Christopher Goulder Cadge, and was born at Loddon on August 11th, 1853. His uncle was the celebrated surgeon William Cadge of Norwich, and in many ways the nephew resembled his distinguished relative, particularly in his very high sense of duty, his unassuming personality, and his generous nature. He was educated at Norwich Grammar School, under Dr. Jessup, and spent a year at the Norfolk and Norwich Hospital before going up to St. George's Hospital. He obtained the diplomas of L.R.O.P. and M.R.C.S. in 1875, and entered the I.M.S. Though posted to the Civil Branch, he volunteered for the Afghan war in 1879, and received the Afghan medals. At Quetta he distinguished himself by the efficient evacuation of the wounded, and as a result was ordered to join Lord Roberts's forces at Kabul, but was not able to get beyond Jumrood Fort in the Khyber Pass, where he found scope for his energy in attending to the large number of sick men of a victorious army, victims of dysentery, rheumatism, and fever. He himself went down with rheumatic fever and was invalided home. He returned to India to take charge of the Lucknow Jail, and when operating on a case of stone poisoned his hand, and was after a very serious illness again invalided home. He returned to take charge of Agra Jail, and then became civil surgeon successively at Fategarh, Aligarh, Fyzabad, Bareilly, and Nainital. During this period he showed great skill as an operating surgeon, particularly in cataract, lithotripsy, and lithotomy. During the great famine he enhanced his reputation, and was on the staff of the Lieutenant Governor, from whom he received a personal letter of thanks. Retiring from the I.M.S. on account of failing health he lived for a time at Lowestoft, where his uncle had also retired. But idleness was irksome, and he obtained the post of medical officer to the Mutford and Lothingland Board of Guardians, where he earned the reputation of an efficient and painstaking officer. During the great war, in spite of his age, he insisted on service, and was appointed to the Ranelagh Hospital at Ipswich, which he largely equipped out of his own means, provided extra nourishment and stimulants for the men, and refused any remuneration for his services. He worked incessantly without regard for his health from 1915 to 1918 at this post, and finally retired with the thanks of his commanding officer, receiving the decoration of O.B.E. for his services. In spite of his failing health Colonel Cadge took a great interest in local affairs; he served on the board of the Lowestoft Hospital, which was the richer for his generosity. He was a keen sportsman, and up to last year a good shot. He was endeared to a large circle of friends by his courteous and lovable nature, his loyalty to his friends, his great kindness and humility, which, perhaps, was a barrier to the high place he could have obtained if he had ever desired fame and high position. His generosity was great, and few knew the extent of his benefactions, both to institutions and individuals. He married in 1882 Miss Flora Summers, whom he leaves to mourn his loss. Our sympathy and condolences are with the widow and relatives.

We regret to record the death of Dr. W. F. R. CASTLE, on July 1st, at the age of 34. His school was Wellington, where he was distinguished as an athlete. Thence he went up to Trinity College, Cambridge, and in 1913 entered the London Hospital. At the outbreak of war he became a surgeon probationer in the navy, and in 1916 obtained the diploma L.M.S.S.A.Lond.; he was then promoted surgeon, and served in the North Sea and the Baltic, winning the Distinguished Service Cross 'in connexion with the Archangel expedition. In 1920 he graduated M.B., B.Ch. Cantab., proceeding M.D. in 1923, and in the following year obtained the M.R.C.P.Lond. After holding the posts of house-surgeon, house-physician, senior casualty officer, and anaesthetist at the London Hospital, and clinical assistant to the St. John's Hospital for Diseases of the Skin, he was appointed physician in charge of the skin departments of the Queen's Hospital for Children, the West End Hospital for Nervous Diseases, and the Kensington, Fulham, and Chelsea General Hospital. He contributed numerous articles on dermatological subjects to medical periodicals, including one on fur dermatitis to the BRITISH MEDICAL JOURNAL in 1924. His outstanding clinical skill, together with his kind, cheery nature, won for him great popularity; and his untimely death has brought grief to his many friends.

## Medical News.

THE Rogers prize, of the value of 150 guineas, for the best essay on the subject of "The treatment of the sick poor and the preservation of the health of the poor" has been awarded by the trustees (Sir John Rose Bradford, President of the Royal College of Physicians, and Dr. T. Vincent Dickinson, Master of the Society of Apothecaries) to Mr. Hugh J. McCurrah, M.B., F.R.C.S. Numerous essays, many of them of considerable merit, were received from different parts of the country and from as far afield as India and South Africa.

THE annual meeting of the Poor Law Medical Officers' Association will be held on Thursday, July 22nd, at 3.15 p.m., in the guardians' board room, Shakespeare Street, Nottingham. The chair will be taken by the president, Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P.; after the formal business Dr. A. L. Baly, superintendent of the Lambeth Hospital will read a paper on the Poor Law hospital, its past, present and future. All Poor Law medical officers are cordially invited to be present.

THE Italian Government cinema film on malaria was exhibited on July 12th, by the Baron Bernardo Quarantini San Severino, at the Royal Army Medical College, Millbank. Dr. Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine, introducing the lecture referred to the value of the Baron's work during the war and subsequently in establishing and strengthening the friendly relations between Italy and Great Britain. The film dealt comprehensively with the whole field of malaria prophylaxis and treatment in the past and present. Diagrammatic illustrations of the processes of the infection of the mosquito and the life-history of the malarial parasite were associated with detailed descriptions of the preparation of quinine and its distribution throughout Italy, and the different processes of drainage and destruction of the mosquito larvae. The lecturer explained the extensive nature of the antimalarial legislation in Italy, and gave illustrations of the value of the work that is being done. Malaria, he said, is gradually disappearing from the world and will soon become an almost unknown disease wherever this systematic treatment is adopted. The lecture had been originally intended for students of the London School of Hygiene and Tropical Medicine, but it was felt that the importance of the subject and the particular interest of the film called for its exhibition to a larger audience, and Sir Holburt Waring, in moving a vote of thanks to the lecturer, emphasized this point.

DR. H. HAROLD SCOTT, F.R.C.P.Lond., D.T.M. and H.Camb., F.R.S.Ed., has been appointed lecturer on tropical diseases at the Westminster Hospital Medical School. Dr. Scott, who formerly held the appointment of Government bacteriologist, Jamaica, and was afterwards Government bacteriologist and pathologist, Hong-Kong, is now Senior Research Fellow and comparative pathology at the London School of Hygiene and Tropical Medicine and pathologist to the Zoological Society of London.

THE Medical Women's Federation has arranged to hold a garden party during the Annual Meeting of the British Medical Association in Nottingham next week. It will be held, through the kindness of Miss Jessop, in the grounds of The Hermitage, on Thursday, July 22nd, from 3.30 to 6 p.m.

THE proposed post-graduate medical hostel at the Imperial Hotel in Russell Square, London, W.C., to which we referred on July 10th (p. 82), will be opened on Monday, July 26th, when an address on the objects of the hostel will be given by Sir D'Arcy Power at 9.15 p.m., under the chairmanship of Dr. Alfred Cox. Prior to the address there will be a general meeting at 7 and dinner at 8, for which the charge is 5s. Medical practitioners and their friends, including ladies, are cordially invited. Further information may be obtained from Mr. A. P. Bertwistle, F.R.C.S., 4, Spital Square, Bishopsgate, E.1. An announcement of the objects of the hostel appears in our advertisement columns this week.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on July 19th, at 3 p.m., Mr. Letchworth will give a special demonstration in clinical ophthalmology at the Royal Eye Hospital; this demonstration is open to all members of the medical profession without fee. On the same date there begins an intensive course in medicine, surgery, and the specialties at the Prince of Wales's General Hospital, Tottenham, with daily sessions for a fortnight from 10.30 a.m. to 5.30 p.m. The West End Hospital for Nervous Diseases will hold a course of lectures and clinical demonstrations on the diagnosis and treatment of common diseases of the nervous system from July 19th until August 12th at 5 p.m. daily. All-day courses will be given at the Queen Mary's Hospital for the East End, Stratford, from August 23rd to September 4th, and at the Queen's Hospital for Children, Hackney Road, from August 18th to 28th, the former being an intensive course in medical surgery and the specialties, and the latter in diseases of children. Practical courses in anaesthetics are arranged at any time to suit post-graduates and usually last about three weeks. Weekly practical courses in obstetrics and child welfare are arranged at the City of London Maternity Hospital; personal application must be made at the Fellowship offices. Copies of all syllabuses and of the general course programme may be had on application to the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

On the occasion of his leaving Ballyjamesduff, Co. Cavan, to practise at New Duston, Northampton, Dr. M. J. McQuaid was presented by his friends and patients with an address, a wallet containing Treasury notes, and a silver tea set.

THE extension of the Dental School at Guy's Hospital, opened on July 8th by the Right Hon. F. D. Acland, chairman of the Dental Board, adds to the number of dental chairs and the number of students that can be accommodated. One room is set apart specially for children, another is a denture room reserved exclusively for fitting dentures and appliances, a third is a demonstration room with the latest devices (including movable tiers on which students can stand); another is a clinical room in which special cases are seen by the surgeon on duty. A very large conservation room has been installed, together with a new prosthetic laboratory in which dentures and appliances are constructed, and a large preparatory laboratory, accommodating fifty students, for teaching the more mechanical side of dentistry. Altogether between 300 and 400 students can now be accommodated. At the ceremony Mr. Acland was invited to open the extension by the senior dental surgeon, Mr. Montagu F. Hopson, who was the first student at Guy's Dental School when it opened its doors in 1889. Mr. Hopson mentioned that in the first year of the school's history the attendances of patients numbered about 4,000, in 1925 they numbered 88,000. During those thirty-six years more than 2,000 students have been enrolled. Mr. Acland, addressing the company in the physiological theatre before proceeding to unlock the doors of the new building, said that the Dental Board had been able to provide £5,000 towards the £23,000 which represented the cost of the extension with its equipment and fittings. The allocation was from funds the Board received from the dental profession as registration fees; but he wished to remind those present, and especially the students, that a very large proportion of those funds had been provided by men who had never enjoyed the advantage of training in such a place as Guy's Dental School. After the dean of the school, Professor T. B. Johnston, had proposed a vote of thanks to Mr. Acland an adjournment was made to the new building.

THE British Consul-General at Marseilles informs us that the Marseilles British Merchant Seamen's Hospital is now complete and ready to receive patients. It has been renamed Queen Alexandra Memorial Hospital (Marseilles). The building fund is nearly exhausted and, though there is no debt, it is not proposed to open the hospital until a satisfactory balance has been accumulated to meet the initial running

expenses; the committee is appealing, therefore, for a sum of £5,000. The hospital contains sixty beds which will provide accommodation for merchant seamen and also for travellers from the Far East and elsewhere. The Duke and Duchess of York have consented to be patrons of the hospital. Subscriptions should be sent to the honorary treasurer, the Chairman of Barclay's Bank, 54, Lombard Street, E.C.3.

THE Cambridge University Press has recently undertaken to publish *The British Journal of Experimental Biology*. It is the official medium of publication of the Society for Experimental Biology, but its contributors are not limited to members of this society nor to the universities of Great Britain. The editor is Mr. James Gray, of King's College, Cambridge, with the assistance of Dr. Crew, of Edinburgh, and of eight other biologists representative of the different subjects concerned.

The Ministry of Health has issued a revised list of treatment centres and clinics for venereal diseases in England, Wales, Scotland, and Northern Ireland.

DR. WU LIEN TEH (G. L. Tuck), Director and Chief Medical Officer of the Manchurian Plague Prevention Service and Physician Extraordinary to the President of China, has received from the Imperial University of Tokyo, Japan, the highest medical degree of *higaku-hakushi*, his thesis being "A treatise on pneumonic plague." Dr. Wu already possesses the degrees of M.D. Cantab., LL.D. Hong-Kong, Litt.D. Peking, Sc.D. Shanghai, and C.P.H. Johns Hopkins. The League of Nations is about to publish a book by him on pneumonic plague.

THE cinematograph industry has collected nearly two hundred films on various subjects to present to the leper hospital of Palo Seco, near Balboa, in the Panama zone.

WE are informed by Dr. Barcroft Anderson that Dr. Carl Spengler is now able to produce in the rabbit a rapidly growing cancer tumour in such site on its surface as he may select, using a pure culture obtained from man of the organism he believes to be the cancer micro-organism, and from this cancer again to isolate the micro-organism. The cancer tumour in the selected site is determined by the injection of a drop of turpentine.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should communicate with their names, not

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9361, 9362, 9363, and 9364** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Basillus, Dublin*); telephone: 4737 (Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*); telephone: 4361 (Central).

## QUERIES AND ANSWERS.

### THE BLUE BAG.

"K." asks: "Is there a widespread belief in the efficacy of blue of bees and wasps. Is it really?"

As its efficacy is unquestioned in most domestic ciras, there must be some grounds for the belief. That being admitted, the cause of its virtue becomes at once a suitable subject of inquiry and a consideration of its possible modes of action is not out of place. Washing blue consists of the colouring matter known as ultramarine. It is a double silicate of aluminium and sodium containing sulphur, and may be made by fusing together

kaolin, sodium carbonate, and sulphur. The sulphur in the compound is in a form kindred to that of the sulphur in liver of sulphur, the sulphurated potash of the *British Pharmacopoeia*. The other components of washing blue have alkaline properties, but are otherwise physiologically inert. As the pain from the sting of a bee or wasp is believed to be due chiefly to the acid injected, it must be concluded that the sulphur contributes nothing to the relief from smarting. There exists no analogy from which to infer that such a compound of sulphur could mitigate pain. It is said that ammonia allays the pain of a sting even more quickly than the blue bag. It might be assumed then that the relief produced by the blue bag is due to the alkalinity of its contents, but the acceptance of this view is checked by the objection that if such were the case washing soda would be better than blue; and, if better, would be generally used in preference, as it is at hand in every kitchen. There is a further difficulty that if the blue bag was good a simple innaction of washing blue made into a paste ought to be better. Again, if that were the case there is little doubt that the paste would have superseded the bag. It is thus necessary to look to the fabric of the bag for an explanation. The idea that the bag may be important is not to be summarily dismissed. After the blue bag has been in use for some time the fibres of its fabric become covered with particles of the less soluble silicates which adhere by an adsorptive property. The film of silicate on the fibres, although but slightly soluble, contains alkali capable of effectively neutralizing acid. Moreover, the fibres are not softened by this alkali as they would be by a solution of soda; they retain a degree of stiffness and are capable of penetrating the puncture of the sting when the blue bag is dabbed on. With a flannel blue bag this quality is more pronounced than with one of cotton fabric. This reasoning seems also to furnish a valid explanation why the blue bag is better than a cloth moistened with solution of soda, for the fibres of such a cloth would not penetrate the puncture. If washing soda is less effective as a simple application than ammonia, this may be because the acid injected by the sting, being of appreciable concentration, at once produces a microscopic bubble of carbon dioxide on contact with the solution of soda. Such a bubble lodged in the aperture of the puncture would stop the entry of the soda.

It has been stated, we seem to remember, that the irritant fluid injected by a bee sting differs from that of a wasp sting, the one being alkaline in reaction and the other acid; but we are not aware that this has been confirmed, and a well informed correspondent insists that both are acid. It seems to be a matter of general observation that the same remedies are equally effective or ineffective in both.

## LETTERS, NOTES, ETC.

### SOUTHWELL MINSTER.

MR. RUSSELL COOMBE (Exeter) writes: It is to be hoped that no member of the British Medical Association who has not already visited Southwell will fail to take advantage of the opportunity which the Nottingham Annual Meeting offers. The nave of Southwell Minster (now cathedral) provides a magnificent example of a Norman nave. One of the original Norman aisle windows remains on the north side and illustrates one of the great disadvantages of the Norman churches—the smallness of the windows and consequent darkness of the buildings. The clerestory windows at Southwell again show the same point. The western door is a fine specimen of a Norman door, but the chief feature of the Norman work at Southwell is the porch on the north side of the nave, which is only doubtfully equalled (certainly not surpassed) elsewhere in England. But the crowning glory of Southwell is the decorated chapter house. Were there nothing else of interest in the cathedral, this alone more than repays even a long journey to see it. Of it Street, the architect of the Law Courts, says: "What either Cologne, Ratisbon, or Weisen are to Germany; Amiens Cathedral or the Sainte Chapelle are to France, the Scaligera in Verona is to Italy, are the choir of Westminster and the Chapter House at Southwell to England." Another authority says: "It is impossible to conceive anything more beautiful. It is the most perfect work of the most perfect style of Gothic architecture."

### EX-RESIDENTS, NORFOLK AND NORWICH HOSPITAL.

THE honorary staff of the Norfolk and Norwich Hospital has issued a circular letter to ex-resident medical officers inviting them to contribute to a fund to furnish rooms for Miss Bindley, known to them all as "Maria," who is retiring from the position of officers' maid-servant after completing over fifty-one years' service. The board of management has granted her a pension. Contributions for the furniture not exceeding 1 guinea may be sent to Mr. Frank Inch, house governor and secretary, Norfolk and Norwich Hospital, Norwich. As there is difficulty in tracing the addresses of all residents it is hoped that those who may not have received the circular letter will act upon this intimation.

### PUERPERAL SEPSIS.

DR. W. B. HUNTER (Londonderry) has written to express the view that it would be well that practitioners should examine themselves before parturition as to the state of the kidneys. He asks how it is that puerperal sepsis is as rife now as it was, say, forty or fifty years ago, when nothing was known of sterilization of hands, or clothes, or instruments by the practitioner. "Before examining a case," he says, "we sometimes

did not even wash our hands, and used any grease or ointment we could come across for anointing the examining finger; when using the forceps any grease was used for smearing the blades, which had for a moment been dipped in some warm water. There was no flushing out of the vagina or washing the external parts with any antiseptic lotion. Antiseptics then were only of use in general surgery, but not thought of in a puerperal case of sepsis was very common. Yet these conditions in medical attendance obtained now amongst the majority of women in childbirth I have no doubt they would die in great numbers of sepsis. The women of the days I speak of were able to obtain and use good wholesome and nourishing, though simple and plain, food, and thereby to resist the action of the toxins or on white in addition. Consequently they fall easy victims to the attacking toxins. They fail to produce Nature's great life agent and protector in sufficient quantity; the streptococci the well nourished and the woman lives. These remarks apply to both exogenous and endogenous pathogenic germs, the latter always being present."

### SMALL BOYS AND WESTMINSTER BRIDGE.

"PRO RE NATA" writes: I was interested to see an account in the public press of a small boy who put his head through one of the trefoil openings in the side of Westminster Bridge and could not get it back again. In 1900, whilst passing over the same bridge, I saw a boy in exactly the same predicament. He was surrounded by a big crowd and two policemen were busy smearing his head with soft soap in an endeavour to get him out. I offered my services and was told by one of the policemen to mind my own business and "get away out of it." This I did, having one or two matters to attend to in the Strand, and on my return two hours later was surprised to see the poor little fellow in exactly the same position but very much the worse for it. I accordingly went to one of the policemen and told him that, as they had been unsuccessful and signs of considerable exhaustion, I might now be permitted to make an attempt to extricate him. At the time they were using a file in an endeavour to enlarge the opening. "All right," said the constable; "if you think you can do better than we can, have a go." Speaking obliquely, the boy had obviously inserted his head in a position of extreme flexion and, after getting it through the opening, had extended it. This could be seen plainly on looking over the side of the bridge, and it was, in fact, the only position in which he could maintain himself fairly comfortably. It was the problem of the after-coming head. I accordingly flexed his head strongly upon his chest. To get his chin well down to his chest I had to push him a little farther through the hole, as his tendency was to pull back and so keep up extension. It took just over half a minute to extract him, amid loud cheers from the crowd. It is a fairly certain thing that if a head can be made to go through one of the openings it can be made to retrace the path by which it entered, and it seems a pity that the bridge should have been damaged to the extent of using a hacksaw, especially as doctors are reported to have been on the spot to assist the police force and the fire brigade.

### PRONUNCIATION OF MEDICAL TERMS.

MR. ALEX. E. ROCHE, M.Ch., F.R.C.S. (London, W.) writes: The derivation of scientific terms is always of interest, but has little effect on the pronunciation sanctioned by usage. According to their transcription from *phthisis*, *diphtheria*, *raportia*, and *raportia*, the first *i* in *phthisis* should be pronounced as shortly as the second; the *e* in *diphtheria* short (as in "error"); the *o* in *parotid* and *carotid* long (as in "dotted"). As we flagrantly neglect etymology in the pronunciation of these and hundreds of other words, why worry about "angina"?

### ALCOHOL MOTOR FUELS.

At the congress of chemists arranged by the Society of Chemical Industry to take place in London next week (July 19th to 23rd) some interesting records will be given of the use of alcohol as a motor fuel. It appears that the Queensland Government, the Distillers' Company, and others are producing alcohol from molasses and starch-bearing crops in Queensland. The German Government has also put on the market a fuel consisting chiefly of alcohol. The tests that have been made with the fuel show that many millions a year would be saved by its use if engines were altered to work on 65 to 1 compression.

### METHOD OF TREATING ASTHMA BY RADIATION.

Correction.  
WE are asked by Dr. S. Gilbert Scott to correct an error in his preliminary note on this subject published in the *JOURNAL* of June 5th. Under the heading of "Technique" (p. 940, col. 1) "25 mm." should read "25 cm."

### VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 52, 53, 56, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 44.

# British Medical Association.

## NINETY-FOURTH ANNUAL MEETING, NOTTINGHAM, 1926.

### President's Address

ON

## THE MEDICAL PRACTITIONER AND THE PUBLIC.

BY

ROBERT GEORGE HOGARTH, C.B.E., F.R.C.S.,

SENIOR SURGEON, GENERAL HOSPITAL, NOTTINGHAM.

My first duty to-night is strictly personal. It is to express my heartfelt appreciation of the great honour conferred upon me. To be President of the British Medical Association is—I hope I speak without bias—to be the President of the finest professional association in the world. I can ruthfully add that no one in the fast lengthening line of my predecessors in office has entered upon the duties of the Presidency with a greater realization of his own inadequacy to fulfil them as they might be fulfilled, or with a more earnest desire to bring to such fulfilment the very utmost of which he is capable.

### THE NOTTINGHAM MEETING OF 1892.

May I next remind you of the Association's last visit to Nottingham in 1892—more than thirty years ago? That was before I came to Nottingham, and I certainly had no visions or premonitions that the next time the Association met here I should occupy this exalted position. What made that Nottingham meeting memorable was that then, for the first time, the Association, by its vote, admitted women to its full membership. I will not rake over the cold ashes of that dead controversy except to say that no one, so far as I know, regrets that decision to-day, or if he regrets it, deems it expedient to say so, or wishes that it had been further postponed. The wonder now is rather that the prejudice—for time has proved that it was only a prejudice—lasted so long.

There is now no degree or diploma, no office, no honour, no post in the medical profession (at any rate on the civil side) which is not open equally to women as to men, and I shall be well satisfied if, in the years to come, the present Nottingham meeting of the Association has as good cause to be remembered with honour and with gratitude, either for some signal reform or some wise and judicious decision, as was the earlier meeting in 1892.

### Nottingham and its Surroundings.

The abundant literature about Nottingham which all of you have doubtless received makes it quite unnecessary for me to sing the praise of a city which has a glorious past, both in fact and legend, a prosperous present, and a future bright with hope. You will be able to judge for yourselves whether report speaks in terms too flattering or in terms not flattering enough of Nottingham's varied charms. All I wish to say is that the local members of the Association are immensely proud of the visit of their colleagues from all parts of the Empire, and are deeply grateful to the civic authorities, and indeed to all who have collaborated so generously in the preparatory work necessary to make the visit a success.

We who practise our profession in this ancient yet modern city by the Trent invariably find all classes of the population singularly responsive to the many and recurrent humanitarian claims of her medical institutions. You will see the evidence of that in many a fine building, and in none displayed more nobly than in the magnificent Home to Nurses, which is built almost on the very spot where

Charles I raised his standard at the opening of the Civil War. The city which chose that home for a war memorial will be proud to show her famed hospitality to those who practise medicine.

### THE MARCH OF MEDICAL SCIENCE.

The decrease in the general rate of mortality is one of the most striking proofs of the rapid forward march of medical science. It has fallen by nearly one-half in fifty years. Had the birth rate been maintained the Malthusian doctrine would have enjoyed a new lease of life, and we should now be talking in awed tones of the "hungry generations" treading us down. But it has fallen by even a larger proportion in the same period, and the net total figures of the population only continue to show an increase because of the longer life.

It is a great triumph that a large percentage of humanity can now so far outrange the Psalmist's three score years and ten, and, instead of the added years entailing heaviness and sorrow, can still enjoy the pleasures of a discreetly ordered table and the beneficent exercise of the veteran's game at golf. By taking thought and following advice we can lengthen out the measure of our days and look forward with some confidence to a green old age. This prolongation of life—active life of course I mean, though the pace may slacken—is, I say, a great achievement in itself, especially if we agree with Scipio's reason for regretting that so few attained old age—namely, that if more attained it life would be lived in better and in wiser fashion.

Yet is there not a real danger of attaching too much importance to the triumphant statistics of mortality without due consideration of their actual content? Mere prolongation of life is of little good in itself, either to the individual or to the nation, unless there is a real capacity to enjoy it. All medical men meet with cases where the efforts made to prolong the life of a patient who is far past effective help hardly seem a kindness to the sufferer and often bring those about him to the breaking-point. Far more desirable than to make a brave show in the statistical tables and increase the number of nonagenarians and centenarians is to raise the general standard of health among all ages of the community.

### The Practitioner's Duty to the State.

Let us look at this question from the point of view of the State, since our duty to the State, according to some people, seems to be reckoned higher than our duty to ourselves. During the war public opinion was shocked to discover that the C3 category was so large in comparison, not with the A1, but with the B's and even with the C's. But it did not surprise the doctors, who knew the long catalogue of disabling ailments which afflict the general mass of the people.

The first sets of figures published by those who medically examined the school children in the elementary schools had already given clear warning. If such distressing percentages prevailed among the children between the ages of 5 and 15, what was to be expected when they grew to manhood? Moreover, a swollen C3 category of men

between 18 and 45 necessarily means a still larger percentage of the same category between 45 and 65, after which year, presumably, very few of these damaged people contrive to earn a livelihood. What is true of the men applies no less to the women, and so we have throughout the country an enormous mass of bruised and damaged humanity which never enjoys robust health, which is continually ailing, which provides a multitude of victims for every epidemic, and which, regarded from the purely economic standpoint, never approaches full industrial efficiency, because it is never fit and alert.

I would not paint the picture in too sombre colours. Most of the world's work is routine work, which can be got through more or less satisfactorily at ordinary times, whether, for the purpose of the military category, a man is classed C3 or B2. Nevertheless, the C3 man will be oftener on the sick list; he will make more mistakes; he will produce less; he will lose his job sooner; and at any moment of emergency he will be less trustworthy and reliable. His physical deficiencies will increase with the passing years; he will be less able to protect himself and his family; he is more likely to seek support or stimulant from alcohol and then begin to suffer from its cumulative effect. Would it not therefore be better for the State if we took pride, not in rewriting the tables of mortality, but in raising the C3 people to a higher category—not in view of distant military contingencies, but for the immediate purpose of rendering them more efficient citizens, more valuable producers of wealth, parents of a healthier stock, and themselves more contented with their lot?

If we regard the great stagnant pools of ill health and the infinite variety of debilitating ailments, deep-seated and chronic, we are driven to the conclusion that physical inefficiency is at once the most permanent and fruitful cause of individual unhappiness and social discontent. Walt Whitman's lines are worth recalling in this connexion:

"I think I could turn and live with animals,  
They are so placid and self-contained;  
I stand and look at them, long and long;  
They do not sweat and whine about their condition,  
They do not lie awake in the dark and cry for their sins,  
Not one is dissatisfied, not one is demented with the mania  
of owning,  
Not one is respectable or unhappy over the whole earth."

Humans are like animals at least in this, that if they are to be happy and contented they must either keep fit or be kept fit; and the honour of being considered the greatest benefactor to mankind belongs not, as is so often said, to him who can make two blades of grass grow where only one grew before, but to him who can add most to the science of health and raise the standard of fitness throughout the whole community. Surely that would be of more instant value to the State than the preservation of infant life in the first year of existence and the indefinite prolongation of what used to be called the allotted span. If there be any who dislike such a comparison of human values, they may be reassured by the reflection that whatever measures are taken to raise the general standard of life can hardly fail to benefit the infant in the cradle and the aged patient in the Poor Law infirmary.

#### *The State and the Nation's Health.*

If these considerations have weight, it must be one of the paramount duties of the State to concern itself more and more intimately with the health of the nation. It can do that by its solicitude for those who are sick, and by taking whatever measures are possible to keep them from becoming sick. Its action, in a word, must be both curative and preventive. While the science of medicine was mainly empirical and the causes of disease were either unknown or wrongly attributed, preventive measures by the State were little thought of. To-day a long series of Public Health Acts and the still recent creation of a Ministry of Health attest the full recognition and acceptance by the State of this essential administrative function. The right of the State and of the public authority to invade this particular domain is no longer challenged. It is seen to be for the common good that the sanitary and the factory inspector are armed with the sanction of the public authority; and as the ameliorative possibilities,

latent in preventive measures, are better understood, there will be a growing impatience with the obstacles placed in the way of their effective exercise by selfish or interested parties.

The establishment of the Ministry of Health bore witness, not to the sudden discovery of a new truth, but to the proved results of much admirable work which had been done in the previous half-century and to the need of its more resolute prosecution. We are now accustomed to the blessings of a pure water supply and efficient systems of drainage and sewerage; we have grown intolerant of the most offensive features of a slum; we have a clearly defined standard of, say, the minimum hygienic requirements of a new house. Throughout the wide field of industrial hygiene we know what conditions are desirable and what are dangerous to health. Our knowledge is fairly complete; the practical difficulties are connected with administration—how to deal with the borderline cases, and how to make the best use of the money at disposal, for improvements are always costly and public expenditure can only be met either out of rates or out of taxes.

Public opinion has to be educated continuously all the time. As a rule it proves amenable to tactful handling. For example, the compulsory notification of diseases is now extended far beyond its original scope to as many as twenty-two notifiable diseases, and will probably be extended much further within the near future. The agitation when the National Health Insurance Act was being passed is now remembered with a smile for the broken vows that were registered never to lick Mr. Lloyd George's new-fangled stamps. But even the greatest changes are very soon accepted as if they had always been, provided that on the whole the new institution functions well and promotes, in spite of whatever defects, the general well-being.

#### *Preventive Legislation.*

The scope of preventive legislation is almost limitless, and we are likely to see the State interfering—or shall I say intervening?—more and more in the interests of public health. For example, all the Licensing Acts of the last half-century are based in the last instance on the argument that stricter regulation is necessary for the general public health and safety, and it is obvious that that particular field of controversial legislation is by no means exhausted.

Moreover, the State is beginning to assert its regulative powers in departments of social and even of family life from which hitherto it has held aloof, and its justification will always be that the interests of public health override the personal interest of the individual, who, as a member of the community, does not and cannot act to himself alone. We may expect sharp controversy, for example, if and when the State concerns itself directly with eugenics, and asserts its solicitude for a generation not yet born, not by the provision of cradles and nurseries, but even by the very determination of parentage itself. This might have seemed fantastic a few years ago. But now that the idol of State socialism has been set up for our worship we may be sure that sooner or later the theorists will attempt to invest the Ministry of Health with increasingly autocratic powers, and will seek to transform the whole medical service of this country into a State service, with State hospitals, State examinations for degrees, and the State payment of doctors. This would be a perfectly logical development in a socialist State, nor can it be pretended that such a system could not be worked. But whether it would be as efficient as our present system, whether it would be as acceptable to the general body of the people, and whether the vastly increased cost would be repaid by equivalent advancement of medical knowledge or improvement in the public health, there is room for the very gravest doubts.

#### *Doctor and Patient.*

The patient's right to choose his medical adviser—which right is indispensable to the creation of a perfect relationship between them—has contributed largely to the smooth working of the National Health Insurance Act. There are roughly thirteen million insured persons and rather more

than thirteen thousand medical practitioners on the panels. These are not, as some ill informed critics of the service would seem to assume, a separate and inferior class of medical men. They are in every sense of the word general practitioners, and the service they give is a general practitioner's service.

To each patient on his list the insurance practitioner accepts the relationship of a family doctor, just as he would do if he were called in by a private patient. He gives to each the skill and the attention within his power, and he gives them, as a rule, cheerfully and willingly, as he has contracted to do. One sometimes hears general complaints of too rapid and casual a diagnosis; but when the waiting room is full the same complaints are not wholly unheard even in the most august thoroughfares of the London specialists. The true test of value of the service given is to be found in the fact that in 1924 only 404 complaints were received by Insurance Committees and investigated by their expert subcommittees, and in only four cases did the more serious charges result in the removal of the practitioners' names from the Medical List.

Is it likely that a better service would be provided if each insurance practitioner were selected for inclusion in the list by some official of the Ministry of Health, and if he were required to give an even more detailed and minute account of his practice and submit still more voluminous reports? The panel would still be composed of exactly the same people, and even if the allotted quota of patients were reduced, is it at all certain that the individual patient would receive a greater share of the doctor's attention?

We know what happens in all State services. The red-tape machine would soon be started; more and more reports would be called for; the doctor might see fewer patients, but the volume of his activities would be in no wise lessened; and the cost of the service to the taxpayer would be enormously increased. You will not make the panel doctor a better doctor by making him more of a civil servant and less of a doctor; nor will you make the thirteen million patients more contented with their treatment.

The reform that is most required in connexion with the insurance service is one which shall link up the insurance practitioner with the consultant physician and the consultant surgeon, and give the insured patient the benefit of the profession's specialized as well as of its general knowledge.

#### THE VOLUNTARY HOSPITALS.

Nowhere is the principle of voluntarism so well worth maintaining as in connexion with the hospitals; nowhere has it been so triumphantly maintained. It is sometimes suggested that the chief virtue of voluntary agencies is to do the rough pioneer work in difficult and intractable places, to create a favourable public opinion, and then, in due process of time, to hand over control to some department of State which will carry on the work upon an altogether larger scale. Indeed, I have seen it stated that voluntarists ought to be proud to merge their small individualities into the larger being of a public department and to lose themselves like rivers in the sea. But the enthusiastic friends of the voluntary hospitals are human beings, not mere charitable machines which function altruistically because their well disciplined hearts happen to be set that way. They are proud of their work. They love it. They see results which encourage and inspire them. They do not want to sink themselves, but to express themselves. The gratitude of those who are healed is sweet in their ears. Voluntarism is the very life and soul of the whole hospital movement.

It is not suggested that the hospitals would wither if the voluntary principle were abandoned. They would still multiply and prosper. Their orderly routine might well show an even more brilliant and imposing efficiency. But the rules and regulations would lengthen. The spirit of the institution would suffer change and lose something—I fear much—of its geniality and kindness. Why is it that such a difference exists to-day between the voluntary hospital and the Poor Law infirmary, which is often better constructed and much better equipped? If you ask a patient to which he would rather be sent, why does he always say the hospital? To some extent the old hard,

unforgettable associations and traditions of the Poor Law still chill the heart. But that is not the whole truth. There is something inherent in officialdom which freezes the genial current of the soul, and thaw it as you will by the application of whatever new principles of kindness and mercy it can never be thawed right out.

#### Hospitals and the State.

Other countries have their State hospital services. Some of you may remember that certain British delegates who visited the show hospital of the Medical State Service of Soviet Russia were enormously impressed by the fresh-water tank in which they saw the live fish which were to serve for the patients' dinners. I wondered when I read the passage how many fish they counted, whether so much as the heads and tails reached the patients in the wards, and whether even this agreeable luxury was much compensation for the complete inadequacy of that particular State medical service to cope with a hundredth part of 1 per cent. of the disease and suffering in Russia.

Let us stand by the principle of voluntarism in the hospitals at whatever cost of energy and patience required for their adequate provision and efficient maintenance. I need not remind this audience that it will take a vast and sustained effort to provide the 10,000 additional beds which the Voluntary Hospitals Commission has declared to be necessary. For that effort the friends of the hospitals will soon have to brace themselves. There is to be no financial assistance from the State. The Minister of Health last February very reluctantly came to the conclusion that no subvention was possible, at any rate at the moment, and so the hope that the Government might repeat its unconditional grant of half a million to the hospitals after the war, in recognition of their invaluable war work and of the utter impossibility during the war period of keeping abreast of their requirements, has been cast to the ground.

Unless this second grant had been as unconditional as the first, I do not know that I am altogether sorry at the Government's decision. If the Ministry had begun to impose conditions of control, it might well have marked the beginning of the end of the voluntary system. I contend that the work done by the hospitals is of such inestimable value, and the confidence placed in them by the public is so well justified, that the State, if it makes any subvention at all, should do so without restrictions, knowing that the money will be judiciously expended. The hospitals should beware of even the mildest beginnings of State control and the relentless, however friendly, grip of any State department.

However, as there is to be no grant these particular anxieties do not arise, and the supporters of the hospitals must shoulder their burden. So large a sum as four or five millions for new capital expenditure will take a very considerable time to raise; for, over and above all this, the maintenance cost has to be found for each new bed provided, and this means an additional recurrent annual cost of £148 per bed. Many of us were disappointed that once again the Chancellor of the Exchequer in the last Budget failed to exempt bequests to hospitals from liability to legacy duty. That is claimed as an act rather of justice than of grace. The toll taken by the State is an interception of charity which is repugnant to good feeling and a sense of fair play to the suffering.

The hospitals, of course, in their turn, owe to their generous supporters the duty of sound economic management, which in turn depends primarily upon the choice of governors. Those which show the best financial balance sheets usually have upon their board of management some outstanding figure of marked ability who has made the local hospital his hobby, his interest, his care, and his pride. However that may be, there must be the undoubted assurance of economic and prudent management if the full support of the public is to be continued. It may well be that a closer co-operation between hospitals—large and small, general and special—is possible and desirable, and that considerable economies might be effected without infringing the real autonomy of each institution, which is so properly and jealously guarded. Charitable effort in this country has always been specially subject to the besetting sin of overlapping and wasteful management; voluntarists

must be ready to face a searching criticism of their accounts by business men whom, if they are wise, they will invite and welcome to their councils.

#### *Changing Type of Hospital Patient.*

Again, we must not shut our eyes to the rapidly changing character of the personnel of hospital patients. The hospital is no longer the lazar-house of the destitute, the place to which homeless and plague-stricken outcasts crawled to die, or into which they were herded if they seemed too noisome and dangerous to be tolerated at large. Such it was in mediaeval times; then came the period, which lasted more or less down to our own day, when the hospital was still exclusively used by such as were too poor to pay for the ministrations of a doctor. Some people still hold that this should be the fundamental function of any hospital which is supported by public subscriptions, and I agree that this primary purpose for which hospitals exist—namely, that of taking in and caring for the indigent poor—must in no way be shelved or neglected.

But we have advanced far beyond that simple conception in these days, and we shall advance much further still, if only because the hospitals, from being mere infirmaries, have become the centres of the best medical and surgical skill in the areas they serve. The best nursing, the latest scientific apparatus, all are concentrated there for the service of the poor, and while the rich and the well-to-do can look after themselves, there remain large intermediary classes of the population who are cut off from the best skill because, on the one hand, they cannot afford the fees, and, on the other, they are not of the class for which the hospitals were intended. If that were pressed it would indeed be intolerable, especially in view of the increasing expensiveness of any serious operation or illness, the cost of nursing homes, and the palpable unfairness of leaving out in the cold the great body of the middle classes, whose financial betterment has by no means kept pace with that of the superior artisan class, and who have been in the past, according to their means, good and loyal friends of the hospitals.

#### *Wards for Paying Patients.*

It is certain, therefore, in my opinion, that we shall see a steady extension of the principle of the paying ward, and even of the paying hospital, for the use of the patient who pays in accordance with his means. In many hospitals to-day all but the very poorest patients are expected to contribute to the cost of their healing, and there is little need to lament the disappearance of the old principle that the hospitals were absolutely free—a principle which, in fact, was often grossly abused.

The interests of the middle classes deserve attention no less than those of any other class. May we not, therefore, look forward to a time when every general hospital will be well equipped with paying wards, or will have a paying hospital in association with it, served by the same staff and the same nurses? A middle-class patient who is a suitable hospital case could be seen by the almoner of the hospital, and, after stating his income and position, terms could be arranged according to means. Naturally that will open up the question of fees for the surgeon or the physician, and some obvious and possibly difficult adjustments would have to be made; but no vital principle that I can see would be endangered by the payment of these special fees, or even by the hospital itself making a substantial profit on such cases which would help towards the maintenance of more beds in the non-paying wards. Such changes are likely to be gradual; we can carefully note what effect, if any, they have upon the flow of subscriptions. Personally, I do not think that the charitable donor is likely to object to a middle-class paying patient receiving a share of the fruits of his bounty. He had a much more valid grievance against those who abused the freedom of the hospital and never contributed a penny to its funds.

The medical profession is generous in accommodating its fees according to the patient's income. But every medical man knows cases where the serious illness of the breadwinner or the wife or child has exhausted the savings of a middle-class home or crippled it with a load of debt. The middle-class patient, moreover, is the principal sufferer from the high fees of the nursing home, another institution

which has a necessary place in our existing system for dealing with the cure of disease, but which is by no means immune from well justified criticism. Is it, indeed, too much to say that the extreme expensiveness of nursing homes—I speak, of course, in purely general terms—is contributing as much as anything else to the extension of the system of paying wards in hospitals and the call for its rapid development?

#### *Working-Class Contributions to Hospitals.*

There is also another important development in process with regard to the hospitals. More and more in the large cities and industrial areas the hospitals are coming to rely upon the subscriptions of the working classes, contributed through a general Hospital Sunday collection or through a direct trade union levy. In this district, for example, the Hospital Saturday Committee are very good friends of the hospitals, contributing willingly, cheerfully, and without condition or stipulation as to the hospital service for their members they will receive in return. This trust is not misplaced. They lose nothing by not dealing in terms of contract and demanding the strict recognition of a right.

Many county hospitals are stimulating interest in their work by forming a collecting committee in every village and persuading the cottagers to subscribe to its funds, almost in the same way that they subscribe to a sick or benefit club. This will necessarily lead to a great extension of the hospitals, for those who pay will expect to receive hospital treatment as a right in case of serious illness. When the small contributor begins to talk about "our hospital," the vitalizing spirit of voluntarism is at work. Open the door to State direction and control and the cold east wind of officialism will contrive an entrance too.

#### *THE GENERAL MEDICAL COUNCIL.*

Another aspect of the relationship of the medical profession to the public has been much discussed of late in connexion with certain punitive action taken by the General Medical Council. This discussion has removed many misconceptions as to the specific purposes for which the Council was created by the Legislature—not, as was too often supposed, to serve as the executive of a powerful professional organization protecting the interests of its members, but as a body entrusted with powers, clearly defined first by Parliament and later by the judges, for the protection of the public against the incompetence and the imposture of unqualified medical practitioners. Practically the only criticism directed against the Council arises from the fidelity with which, in these days of growing laxity, it has maintained its jealous regard for the purity of its register of membership. There are really two main questions in which the lay public is interested. The first is: Is it or is it not to the public advantage that the General Medical Council should set its face like flint against professional self-advertisement? The second is: Is it or is it not to the public advantage that the Council should show a less uncompromising attitude towards the unqualified practitioner and a greater leniency towards those who transgress its stringent rule against covering?

The rule against professional self-advertisement is unquestionably in the public interest. The publicity agents of the commercial world may sound their slogan as they will about "Truth in advertising." But, as Dr. Johnson once shrewdly observed, the secret of advertising is "large promise"; and large, limitless, boundless promise is wholly out of place in the practice of the medical art. Inseparable from quackery, it is the sign manual of the unqualified nostrum-monger. In my view, this most salutary rule against professional self-advertisement needs to be observed more than ever now that the old reticences are being broken down in so many directions, and in view of the growing disposition to discuss all medical subjects freely in the public press.

Whether we like it or not, that school of thought is prevailing which holds that the open forum is the best of all popular educators, that ignorance is the greatest of all dangers, and that publicity alone can create the new public opinion out of which it is hoped there may issue a higher moral sense and a stronger self-control. The

public press will devote more and more space to the manifold problems of public health, and it is obviously desirable that what is written should be written with authority. No anonymous article on a technical or professional subject carries the weight of the signed contribution, and if doctors write for the lay press, as they will be urged to do with an ever-increasing insistence, the opportunities of professional self-advertisement will greatly multiply.

Nevertheless, it is to the common interest of the profession and of the public that these temptations—not, indeed, to inform the public of what is for its good, but to inform it in such a way as to advertise and glorify the writer and conduce to his personal gain—shall be resisted, and that the Medical Council shall still continue to exercise its powerful restraints. In other countries a different practice may be followed, but till it is shown that their method is more conducive than ours, either to the dignity and character of the profession or to the protection of the public from the charlatan and the quack, these restraints should not be weakened. Many borderline cases are bound to occur as they do at present, but I assume that the Council will continue to act with that judicial discretion which has on several occasions received the acknowledgement of the highest legal authorities.

#### *Unqualified Practitioners.*

As for the unqualified practitioner, I say without hesitation that the Medical Council cannot and must not recognize him, and therefore cannot and must not abate its strong reprobation of covering. To do so would be to stultify itself and the *Register*, which is its special creation and instrument. It cannot, to borrow an expression from another profession, recognize any orders but its own. I do not mean that it should seek to induce the State, as is done in some countries, to make unqualified practice illegal. Even if that were desirable, the public would not permit it. Public opinion, if I may say so, has a sporting fancy for the outsider, and outsiders, even the rankest, do sometimes win. But, though rare and exceptional cases may arise, the Council cannot extend either the bow of friendship or the nod of recognition to any unqualified practitioner without placing itself in a false position. If an unqualified practitioner really discovers a new cure or treatment for one of the ills of humanity, his consulting room will not long remain empty of patients. If his method is genuine it will endure, and, soon or late, it will win general recognition. But no one can reasonably expect admission to the *Medical Register*—or to any appendix thereto—by any except the approved channel.

Admission is not a question of initiation and secret rite; it is a plain question whether the entrant has gone through certain courses of medical training and passed the presented examinations. How can either be abandoned with safety to the public interest? The unqualified practitioner may or may not have sufficient general medical knowledge to enable him to make a diagnosis. A few may have gone through some sort of a medical course; the majority have not. It takes the ordinary medical man five years or more to complete his course; the unqualified man often does not give as many months. He professes to be a specialist without even elementary grounding in the essential rudiments of medical knowledge. I say nothing against the science of osteopathy or these uses of the manipulative treatment. I only say that those who practise these arts should have the medical knowledge without which they may do their patients infinite harm.

The champions of the unqualified practitioner fall into two main classes. One consists of those good people, invincibly credulous and optimistic by nature, who chatter about cures and treatment as others chatter about politics, and on whose ears well-syllabled words like "osteopathy" and "manipulation" fall with a sweetly modulated cadence of solace and hope. The other class consists of the ingenious rebels against all authority but their own, the sophists of the day, who deride professional etiquette and grimace at professional tradition. Perhaps here and there certain solemn pomposities do linger even yet in our profession, and an occasional grin at these may do no harm; but the health of the public is no grinning matter. The

plain truth remains that behind the rare—the very rare—unqualified practitioners of whose success so much is made, but whose failures pass unrecorded, there are scores of other practitioners of technique ancient and modern. Chaldean and transatlantic, who are eager to take advantage of any momentary opening of the door, which it is the declared policy of the General Medical Council to keep tightly shut.

A selfish, obscurantist policy would be totally contrary to the free spirit of inquiry which animates the medical science of to-day. But this is neither selfish nor obscurantist. Whatever in any modern technique is tested and proved good is sure of eventual adoption, and not even the gates of the General Medical Council will prevail against it. But the tests and the proofs must be such as are recognized by that universal medical science which talks a common language throughout the world and which alone can securely judge.

The public mind was perhaps never more impatient of authority than it is to-day. Unable to distinguish with certainty where the trained expert alone has any claim to be heard, multitudes of people are still prepared to accept offhand the morning and the evening stunt of their favourite newspapers, which are then forgotten as soon as read. So many romantic impossibilities of yesterday have become the casual scientific commonplaces of to-day that the very word "miracle" itself has shrunk back to its original connotation, and even the wisest have still no effective retort to Hamlet's gibe as to the inadequacy of their philosophy to embrace the content of heaven and earth. Nevertheless, Authority remains unshaken on her intellectual throne, though the gusts of change may a little disorder her raiment, and Authority herself acquires a ripper wisdom and a larger experience with the passage of the years.

The medical profession is a living profession. It is for ever breaking new ground, mapping and charting as it goes, and the necessary correction of a too hasty observation or faulty induction, as well as the need to include new knowledge, requires us from time to time to revise our atlases. And though we may be fairly confident that the older continents are now accurately charted, there is always the need to be prepared for the crash of old-established notions and for restless movements of insurgence along boundaries which once appeared to have been fixed for all time.

It is a sobering reflection that, but for the violent wrench out of its true direction which medical science suffered two thousand years ago, some of our most recent discoveries might well have been among the oldest blessings to suffering humanity. With the abandonment of the one true scientific method of patient observation and careful induction there was also unhappily discarded that sagest of all the medical maxims of ancient Hellas, that the physician is the servant of Nature.

The human race has suffered sorely because medical art and science took so tragically wrong a turning, after making so brilliant a start. Probably the perversity of the patient was largely responsible. Popular demand has always been insistent for the bottle of medicine and the charm. Science, under the lead of Aristotle, had sought to exorcise the potion-monger and the thaumaturgist, but back they came with a rush, and when the ancient scientist candidly admitted that he was uncertain as to the nature or the cure of the complaint the patient soon betook himself to one who promised a safe, quick, and pleasant cure.

The great truth that the supernatural and the scientific do not run well in double harness needs, I believe, a resonant restatement to-day. The profession is often blamed for its instinctive repugnance to the introduction of the supernatural into the art of healing. This is attributed to that professional jealousy which is supposed to seize every doctor when an unregistered hand assumes the gold-headed cane which is the symbol of his craft. I do not know that there is more professional jealousy among doctors than there is among lawyers; I doubt if there is as much as among plumbers and bricklayers.

No professional body loves an outsider who usurps its own particular functions, and long experience has shown

that the unqualified practitioner of medicine is in double measure an unqualified danger to the public. And yet how clients troop to his door or rain in upon him a shower of post-office orders if he is a shrewd exploiter at once of the foibles and the earnest longings of mankind. So it has ever been; so it will ever be. As the cynic long ago said: "If the public want to be deceived, let them." But the obvious fact is that the public want not to be deceived but to be cured, and that is why, if an authorized prescription in our cryptic Latin fails to bring relief, they will cheerfully take a free medical tip in plain English from their Sunday paper's answers to correspondents, or accept as gospel the large promise of displayed advertisement; or if they are of a more serious and contemplative type, they will haunt the temples of those who say that they possess the secret of permanent good health.

#### *The Religious Healer.*

With respect to the religious and quasi-religious healer, the medical profession is in a difficult position. It is precluded by the memory of its own empirical past from adorning its robes with the fragile fringes of infallibility. Dedicated to Science and conscious of boundless horizons still beyond its ken, whatever face the profession may present to the outer world, it must display in the intimate presence of Truth the modesty of the neophyte. Nor can it refuse to acknowledge the sincerity of other searchers after truth travelling upon roads other than that on which its own feet are set. Nevertheless, the profession owes to itself and to the public the duty of speaking out.

There is no difficulty, of course, in dealing with the vulgar quack who sells a bottled panacea to the joint benefit of himself and the Inland Revenue, and who leaves the deluded purchaser, if he be lucky, much the same as he was before. But obvious difficulty arises when a new theory and practice of the art of healing is proclaimed and health is taught in terms of religion, and religion in terms of health. In that company the medical scientist has no place. His facts are not theirs. Their terminology is not his. There is no meeting ground in common. He knows what he understands by science; he does not know what they mean. Even if he were willing to join the new cult, its complete refusal to recognize the need of a medical art, such as that which he practises, must effectually keep the door of communication closed. Science has long since framed her own laws of method and proof which are recognized throughout the world, and the medical profession can have no commerce with any newly organized cult which denies the very bases on which these laws are founded.

But this is not to say that no friendly co-operation is possible between doctors and those who are earnestly studying the healing power of the mind. Let there be no contention about names; when we speak of mind or soul, let us freely admit that we cannot take a specimen of either on a slide and put it under a microscope. That there is a certain healing power, a *vis medicatrix*, in religion as in nature, few careful observers would, I think, deny. Between religion and nature, between mind and body, there exists not an opposition but a relation. Every medical man of experience must have known cases in which his own scientific skill has seemed to be helped, sometimes most strangely and wonderfully, by some serenity of mind in the patient, some quiet confidence in the ultimate issue, some realization of sure dependence upon a higher power, some tranquillizing influence of the soul upon the physical stress and tumult of the senses—beneficent, soothing, healing activities in which he and his art have had little or no share.

These facts are not reducible to formulae. Science cannot explain them as she can explain the operation of an anodyne stealing along the passage ways of sense. We do not, indeed, know very much about that mysterious parallel road, which always lies in deep shadow, where the mind or the soul, reacting to a spirit which seems to come from without, influences profoundly in its turn the body which the doctor is trying to heal. There is no place in respect of this region for dogmatic utterance; but there is always room for patient and reverent inquiry. The

whole of our profession will await with impartial mind the result of the labours of the joint committee which was appointed some months ago to investigate the phenomena of what is generally called spiritual healing.

Meanwhile, I say with confidence that any systematized creed which professes to dispense with the art of medicine and surgery is false to the Divine. But if any possess the precious gift of ministering to the mind diseased or of imparting to those who walk in the shadow of the valley the courage to move serenely among the phantoms and terrors which haunt that road, let us be sure that so divine a gift can only emanate from a divine source, and let us welcome the help of any unseen wings that stir the air with healing.

In such moments the old tradition is confirmed that the doctor stands in a different relation to his fellow from most other professional men. I do not claim that the doctor consciously lives, like the priest, what is called a dedicated life—though I have known men to whom that noble phrase might well be applied—but there is a special nexus between doctor and patient which is independent of, as it is unpurchased by, the fee which passes between them. The public expect much of the doctor and take much for granted. I like that old story of the woman of Selkirk who, observing her doctor ride by, said to the neighbour with whom she was gossiping, "Aye, there goes the doctor—honest man! He's brought all my ten bairns into the world and never got a rap for one of them."

The national health insurance scheme has at any rate checked the more unconscionable draughts which once used to be made upon the deep well of medical disinterestedness, but the profession still gives much for which it receives no direct return but gratitude, and sometimes even that is left unspoken. That, however, is the penalty of altruism and an established reputation for kindness of heart, and that is partly why the doctor holds his place in the public esteem, despite the satirists, the playwrights, and the novelists who still delight to poke their fun—on the whole not unfriendly—at his etiquette, his bedside manner, his scraps of weird Latinity, and the artifice with which the wild surmise of an impossible diagnosis may still be masked under the grave, slow smile of apparently assumed certainty.

#### *THE REAL DOCTOR.*

But if we want the portrait of the real doctor we go, not to books, but to life. We expect him, not in vain, to combine with knowledge the understanding that springs from intuition till it is most richly reinforced by experience, to bear a tranquillizing influence, and to radiate confidence and hope. We expect him to exemplify, like the surgeon of whom Henley wrote:

"Faultless patience and unyielding will,  
Beautiful gentleness and splendid skill,"

caring always for life as a thing most precious, quick—and now happily well able—to spare the sufferer one unnecessary pang, the restorer of health, a strong sure help in the more supreme moments:

"In many a house of care, when pain has forced a footing there,  
And ther's a Darkness on the stair will not be turned away."

Such is the doctor, the family doctor, who is more to the public at large than the most learned and the most wise who dwell in those two long, unlovely, parallel streets of London, where the waters of healing are laid on at the main. He is still the same, even though he is called upon in these days to enter the service—the preventive service—of the Ministry of Health, disarming disease before it strikes, saving the firstborn, not by a smear of blood on the lintel, but by a dash of disinfectant in the drain, and sometimes purchasing the immunity of millions as cheaply as the restoration of a few convalescents to health. The doctor's professional qualifications may change as medical science advances; the qualifications he needs to win him the confidence of his fellows are unchangeable as human nature itself. That confidence it is the policy of this great Association and the desire of every one of its members always to deserve and for ever to retain.

# The Maudsley Lecture ON THE PREVENTION OF INSANITY.\*

BY  
PROFESSOR GEORGE M. ROBERTSON,  
IDENT OF THE ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

## (ABSTRACT.)

PROFESSOR ROBERTSON divided his subject into two parts: the influences which go to the causation of insanity; and, observations on the theories and methods of prevention, particularly of general paralysis of the insane. Statistics he used were taken from the twenty-first report of the Commission in Lunacy of the State of New York for the year 1908-09.

### Conditions and Influences Affecting the Occurrence of Insanity.

From these statistics it appeared that insanity under the age of 15 was quite negligible and if included in statistics of insanity had a most disturbing effect, as this age of life comprised nearly a third of the population. The birth rate and a low infantile mortality would increase the population at this period, and the effect of a proportionate increase would be to reduce the apparent rate of insanity in the total population, without any diminution of insanity. A fair number of admissions occurred between 15 and 19, and a larger number between 20 and 24. The amount continued very high up to 40 years of age, after which it fell, so that it appeared that the years of life were the most liable to insanity, and increasing years a mental breakdown became every more remote. But these statistics did not represent the incidence of the liability to insanity—that is to say, the frequency with which insanity occurred in proportion to the number living. The large number of admissions between 20 and 40 was mainly due to the large number of persons living in early life, and the small number of admissions at 75 resulted from the small number in old age. Statistics of incidence showed that insanity tended to develop between 15 and 19, but became more pronounced between 20 and 24. This was followed by a steady rise year after year till the age of 40 was reached. There was then a short period of decline, after which there was an extremely rapid rise in old age. There was a general tendency for insanity to become more prevalent as one grew older. To emphasize the difference between the number of admissions at the various ages and the rate of incidence of insanity at these ages Professor Robertson brought the two charts together for the purpose of comparison.

FIG. 1.—Graph of total number of first admissions (5,222) compared with rate of incidence of insanity per 100,000 of the population at sequential age periods (ratio 3 to 1).

### Incidence of Insanity among Males and Females.

With regards sex, insanity occurred among males at a proportionately higher rate than among females. This unexpected result was mainly due to the greater number of admissions from general paralysis and alcoholic insanity.

Presented before the Royal Medico-Psychological Association on 15th.

Among the married the incidence of insanity was decidedly low. It was slightly higher among women under 35 than among men, and this was no doubt connected with the risks of child-bearing. The loss of a husband or a wife increased in a marked manner the incidence of insanity. Up to the age of 55 the prevalence of insanity among widows and widowers was almost double that among married men and women. The symptoms of insanity in these people were to a large extent a wrong method of adjustment to difficulties in life, and the increased amount of insanity among widows and widowers was both a sociological and a biological phenomenon. Between the ages of 25 and 55 the prevalence of insanity among single men and women was nearly three times as great as among a similar number of married men and women of the same age. The causes of this high prevalence among the single were involved; but the average health of the single was probably lower than that of the married, for ill health might be itself a reason for remaining single. Professor Robertson concluded, from the low incidence of insanity among the married, that the condition of marriage and of family life, in spite of its greater responsibilities, perhaps on account of them, was the most favourable mode of existence for men and women. Young men between 25 and 35 years of age continuing bachelors died on the average four years sooner than married men, and ran three times the risk of becoming insane.

### The Three Critical Periods of Life.

Coming to the three critical periods of life, all connected in some measure with the function of sex, Professor Robertson remarked that during pubescence and adolescence the balance of the internal secretions of the body was disturbed by the intrusion of the internal secretion from the sexual glands. For all practical purposes insanity occurred for the first time at this period of life. Leaving on one side the effect of heredity, there was in insanity almost always a physical cause, but usually combined with mental causes. The physical cause in adolescent insanity was the physiological disturbance produced by the internal secretions. The mental cause was the change in the social status of the young adult or adolescent. He had to adjust himself to the problems of life, and of these the most disturbing during these early years were those connected with sex.

The next critical period was the climacteric, occurring between 45 and 50. This was the age when the powers first began to fail; an age when to keep abreast of younger competitors increased effort was needed. When the climacteric had been surmounted, the incidence of insanity for a period fell steadily. This period, accompanied by a damping down of the fires of emotion, was one of the most valuable. The mind had become stabilized. Wisdom had increased with experience of life. Men of this age guided the destinies of mankind. The third crisis, said Professor Robertson, was known as the grand climacteric, when the period of senescence began. After the age of 64 the rate of incidence of insanity mounted year by year with extreme rapidity, and was proportionately almost double that of the period of adolescence. Above 75 it was almost treble. The incidence was more marked even than was recognized, since many senile persons were cared for at home and were never registered as insane. The crisis of the grand climacteric supported the regulation of the Civil Service that 64 was the age for retirement.

### Heredity, Acquired, and Senile Insanity.

Professor Robertson then divided insanity into three distinctive types—the hereditary, the acquired, and the decadent, associated with three age periods—early adult life, middle age, and senescence, although not limited to them.

He said that the number of admissions of dementia praecox was large, that it was malignant in character, that only 15 per cent. of those afflicted with it recovered, so that the majority of the patients became permanent residents and filled mental hospitals. This gave the impression that the early period of life was the most liable to insanity, whereas adolescence was actually the least dangerous period of life for insanity in general. If, however, we refer to the hereditary insanities alone, and

especially if we restrict our attention to the most malignant type of insanity, dementia praecox, then adolescence is undoubtedly a dangerous period of life. As the individual grew older the danger of a breakdown from dementia praecox grew less. Between 40 and 45 it was exactly half of what it was between 20 and 25.

Manic-depressive insanity, the other important form of hereditary insanity, was not so prevalent in early adult life as dementia praecox, but its hereditary character was displayed by its tendency to recur. It was the benign type of hereditary insanity, and the vast majority of patients suffering from it, who were in good bodily health, made excellent recoveries. Manic-depressive insanity, being a disorder of the emotions, was more frequent among females than among males. The disease in males might be wrongly diagnosed as alcoholic insanity because the patients had taken to drink. In the elated phase of the disorder the patient drank because of his high spirits, and in the depressive phase in order to drown his sorrow.

The two most important forms of insanity in middle life were alcoholic insanity and general paralysis of the insane, and both occurred more frequently in men than in women. Both of them were acquired forms of insanity, and therefore preventable. The diagnosis of alcoholic insanity was uncertain, and depended largely on the personal equation of the observer. The part played by heredity created uncertainty in every case. To suffer from alcoholic insanity one must first be alcoholizable by hereditary predisposition. Alcohol, according to Féré, was the "touchstone of mental equilibrium," and to be able to resist the toxic effects of alcohol betokened a well controlled mind and a sound brain. Mercier had pointed out that there were always two factors in the production of insanity—an internal and an external. The internal factor represented the hereditary tendency; the external, some exciting cause in the environment. These factors were always inversely proportional. If the internal factor or hereditary tendency to insanity was strong, then the external or alcoholic factor was weak; but if the hereditary predisposition to insanity was slight, then the exciting cause must be strong. The graph of alcoholic insanity in

FIG. 2.—Alcoholic insanity and general paralysis. Male and female admissions separately per 100,000 of the population.

males was as perfect as the outline of Fujiyama. The sharp apex of the cone seemed to indicate that there was in the male a climacteric which corresponded to the female menopause.

The incidence of general paralysis of the insane in both sexes resembled that of alcoholic insanity. It reached its period of maximum incidence five years earlier than was the case with alcoholic insanity. Its onset was probably determined by the date of infection by syphilis. We are now in possession of two promising forms of treatment—namely, benign tertian malaria and tryparsamide. In early cases after malarial treatment about a third of the patients were able to return to work, and another third were distinctly improved. Apparent recoveries had also been effected by tryparsamide alone, which was by far the most potent arsenical preparation for the treatment of this disease.

The mental decay of old age would come, said Professor Robertson, to every human being if he lived long enough;

but no physiological process showed more extreme variations than the time of onset of senectitude. Senile insanity was closely related to the waning of the bodily functions and to those diseases to which the aged are liable. Dr. John Carswell had made some interesting observations on the relation between the death rate and the occurrence of insanity. He selected ten wards in the city of Glasgow with a combined population of nearly 400,000, and divided them into two practically equal groups, the one with a death rate below, and the other with a death rate above, that of the whole city, called for convenience the healthy and the unhealthy groups. He also subdivided each group into two sections, the one consisting of persons between 15 and 44, and the other of those above 45 years of age—in other words, a younger and an older section. Dealing first with the younger sections, and making use of first attacks only, Dr. Carswell found that in three years there were 165 cases of insanity in the healthy group and 186 in the unhealthy group. This difference was slight, so he concluded that health of body was probably not the main factor in the production of insanity in the early period of life; 67 per cent. of the cases were due to constitutional or hereditary influences. Dealing next with the older sections he found in the unhealthy group 149 cases of insanity, as compared with only 91 in the healthy group—an increase of 61 per cent. He therefore concluded that ill health of body was an important factor in the production of insanity, being less in a district in which comfort was enjoyed and the death rate was low. Improved social conditions did not apparently lead to any marked diminution in the amount of insanity during early adult life, as the forms of insanity were then mainly hereditary. They apparently reduced the amount of senile insanity.

The preventive aspect of his survey, said Professor Robertson, fell naturally into a consideration of the measures to be taken to deal with the three types of insanity—the hereditary, the acquired, and the senile.

#### *Prevention of the Hereditary Insanities: Eugenics.*

It was sometimes alleged, on the original authority of Morel, that when insanity made its appearance in a stock it arose at an earlier age and in a more severe form in every subsequent generation, so that in the third or fourth generation it was represented by imbecility and idiocy, and the stock came to an end. This progressive degeneration was described by Sir Thomas Clouston as Nature's method of killing off a bad stock. There were errors as well as false suggestions in these statements. When insanity first made its appearance in a stock there was no necessity for it to continue, far less to arise in an earlier and more severe form in each successive generation. If bad stock married into bad, the offspring was naturally less fit than either parent, and if this policy were continued for two or three generations the family ultimately came to an end. But, just as insanity might appear in a family previously sound, owing to unfortunate mating, so it might also disappear, when it had once occurred, owing to propitious unions. Maudsley wrote: "The two principal modes by which an insane strain in a family is worked out of it are, first, propitious unions in marriage, with sound stocks, whereby it is attenuated, neutralized, perhaps ultimately extinguished; and, secondly, propitious dispositions of the circumstances of life." Of these methods he remarked that without doubt the first was most effective. In a process allied to progressive degeneration to which Sir Frederick Mott had given the name "antodating or anticipation," an hereditary form of insanity, usually dementia praecox, appeared in offspring at an earlier age than an attack of insanity in the parent. These precocious attacks of malignant insanity Professor Robertson believed to be the result of unpropitious unions. They indicated that the hereditary tendency in the offspring was greater than it was in either parent. It was clearly a social duty on the part of those inheriting a neuropathic strain to avoid marriage into stocks with a similar weakness, if offspring were expected. In the case of those with obvious mental defect or subject to a severe psychosis, marriage should not be contemplated. Belief in the evil effects of the marriage of cousins had sunk deep into the

popular mind, but in itself consanguinity did no harm, provided the stock was good. As for the question of sterilization, Professor Robertson was not convinced by the theoretical arguments in its favour. He believed the bulk of the medical profession regarded the proposal as such an outrage on their traditional ideals of duty towards their patients that its adoption was impracticable in this country. He could not imagine a board of physicians calmly sentencing a victim to this cold-blooded and superfluous insult. Enthusiasm had overstepped the bounds of reason when a writer declared that "if sterilization should be permanently prohibited, it will be impossible to prevent a slow but steady deterioration of all such civilized races as are so strongly endowed with human sentiments as to prevent infanticide from becoming a permissible practice."

In support of his views on this subject and to show how little the extent of mental disease was appreciated, Professor Robertson quoted an inquiry by Sir Thomas Clouston, who found that in three generations in 41 of 83 families with which he was acquainted in a country parish in Scotland one or other of four diseases had occurred—namely, mental disease, congenital imbecility, idiocy, or epilepsy. Sir Thomas Clouston had no doubt that if his information had been quite perfect, a few more families would have been found to have produced those diseases. The lesson of this study in heredity showed how much room there was for the practice of mental hygiene, of moral control, of abstinence from deteriorating agents, of cultivating good health, and of arranging marriages on right principles, to counteract, and in time perhaps to eradicate, those morbid nervous and mental tendencies.

#### *Mental Hygiene of Childhood and Adolescence.*

To eradicate "morbid nervous and mental tendencies," Professor Robertson continued, is the avowed aim of eugenics, and stripped of excrescences eugenics might one day help to lay the foundations of a healthier and a more efficient race. That goal achieved, it must still be remembered that the task of producing healthy-minded men and women does not end. Every human being is a living and developing organism, bound by his nature to react to the influences of his environment, especially so if they were brought to bear on him during the most plastic phase of life. Even the defective child showed the influence of discerning management and an environment adapted to its responsive capacity, a consideration which went far to justify the large expenditure of public funds in the provision of special institutions and schools for this class. But the advantages so laboriously acquired were squandered by making indifferent provision for lifelong care, and the rectification of this failure was one of the necessities of our time. There was also need for the earliest possible recognition of mental defect, and for a closer study of the ante-natal as distinguished from the hereditary conditions of defect.

In Professor Robertson's opinion the mind of man was not born—it was made. At the outset all those forces which left their imprint on the child were combined in the personality of the mother, and practical hygienic measures must be concentrated on her rather than on the child. The subsequent development of the child involved the transition from the state of dependence to comparative freedom. The social instincts had to be developed through contact with the other members of the family, and later with the community at large. Home influences had subsequently to be tempered by the discipline of school life. Through such experiences the primitive, self-seeking tendencies were subordinated to the higher self, and their latent energy set free for the achievement of social ends. The danger inherent in this long travail was lest in the end the primary instinctive tendencies should triumph over the educative influences. Out of the failure to master the temptations was born the type of temperament in which the seeds of dementia praecox and other forms of mental disorder found a congenial soil. Without doubt, the mental hygiene of childhood and of adolescence played a most important part in the prevention of insanity.

Professor Robertson applied the term "prophylaxis" to particular steps taken with the immediate object of pro-

tecting the mind when threatened by danger. It was essential, for example, to those with a known hereditary predisposition who had already suffered from an attack, and especially to those in whom the attack had been of a recurrent type, such as manic-depressive insanity. When such a case occurred it should be borne in mind that the other members of the family inherited a similar predisposition. The warning indications were, first, loss of sleep. Extreme or prolonged insomnia was a danger, and precautions should be taken. Secondly, there was prolonged anxiety that could not be dislodged. Another danger signal was mental and physical exhaustion. A change of character, not amounting to actual insanity, was another important sign, particularly in those who were subject to manic-depressive insanity. Sometimes the patient was morbidly elated, at others he was morbidly depressed. These changes of mood could be controlled only to a limited extent, but much could be done to prevent their exaggeration into something definitely morbid.

#### *Early Treatment.*

It was believed by many that some of the cases receiving treatment for the prevention of insanity would not develop insanity were they to receive none. Such authorities believed that these cases of the psycho-neuroses, which others regarded as exhibiting the early stage of insanity, suffered really from a definite type of mental disorder of a different kind. It was even alleged by them that the presence of a psycho-neurosis was a protection against insanity. Professor Robertson was inclined to agree that once a psycho-neurosis had assumed a definite form, although it varied from time to time in its severity and in the details of its symptomatology, it did not tend to alter its character, or to assume that of insanity, any more than one definite form of fully developed insanity tended to alter into another. To this extent the treatment of the psycho-neuroses was not the early treatment of insanity, nor could such treatment claim to prevent insanity from developing where that danger did not exist. To this extent also the existence of a definite type of psycho-neurosis, except in rare instances, might be said to protect the individual from the occurrence of actual insanity. But at an early stage it was impossible to foretell whether transient, vague, and disorderly mental phenomena would develop into a typical psycho-neurosis or into a definite form of insanity. There were two stages—an initial stage when anything was possible, and a later stage when the type was fixed.

#### *Prevention of the Acquired Insanities.*

In the middle period of life the benefits of prevention were more noticeable because they were more immediate. Insanity at this period was largely acquired, and could often be prevented. Myxoedematous insanity, for example, had diminished almost to the vanishing point since the discovery of its cause was made. Just as heredity was a factor to be reckoned with to a greater or less extent in every case of insanity, so we were beginning to recognize that disturbance of the internal secretions played a more or less important part in all forms of mental disorder. Any future great therapeutic discovery in the domain of mental disease would probably be found in a knowledge and control of the internal secretions.

Professor Robertson then said that as regards the prevention or abolition of alcoholic insanity there is a very simple way of effecting this, provided it is voluntary. But even if alcohol were prohibited, not in the legal but in the real sense, the total number of cases of insanity would not be diminished by the full number of cases diagnosed as alcoholic insanity. Many of these, owing to inherent instability, would break down from other causes in the absence of alcohol. On the other hand, alcohol is a contributing factor but not the principal cause of insanity in many other cases, and in these abstinence might be the means of averting insanity altogether. Alcoholic insanity is diminishing, though not so rapidly as most people desire. The habit of drinking is on the decline, and it is no small boon that drunkenness is on the decrease and in some places has entirely disappeared.

The other important form of acquired insanity is general paralysis. An astounding fall in the number of deaths was

recorded in 1919, and this has continued, and is of supreme interest from the point of view of prevention. From 1907 to 1918 inclusive the number of male deaths was steady, and for eight years the biennial numbers did not vary more than 10. In 1919-20 there was a sudden drop of 26 per cent. The following appears to be the probable explanation of this sudden fall in the number of deaths. General paralysis may appear within three years after syphilis has been contracted, but it is not till seven years have elapsed that it occurs with any frequency. Of those attacked more than a half die within two years after the first appearance of the symptoms, which are usually present for a year before the patient is admitted to a mental hospital. If, therefore, persons develop general paralysis seven years after infection, and if a half die within two years, we require to go back nine years to find an explanation for any variation in the death rate. In other words, to explain a sudden fall in the number of deaths in 1919 we require to investigate conditions in 1910. If this be done an explanation is found in the employment during that year of salvarsan and the cure by its use of those males who contracted syphilis. As the fall in the number of deaths in 1919-20 is 26 per cent., it is certain that many who had contracted syphilis previous to 1910 and 1911 also took advantage of the discovery of the new remedy.

FIG. 3.—Numbers of deaths from general paralysis in England and Wales in biennial periods from 1907 to 1924, males and females separately. Graph of females four times enlarged as compared with graph of males.

The above chart has been designed from the number given to illustrate the deaths in biennial periods, and as the proportion of deaths of males to females, is about 4 to 1 the graph for females has been enlarged four times to make its variations comparable. The graph for females is remarkable. There is a steady fall from 1907 to 1918, which amounted in that year to 28 per cent. Great as this reduction is, it cannot be attributed to the treatment women received, as comparatively little was done for them till venereal clinics were established in 1920. The explanation of this fall is believed to be as follows: Syphilis is infectious, and in dealing with infectious diseases the treatment of the individual case is of less importance than the prevention of the spread of infection. During the first decade of the century treatment by mercurial inunction was employed, and this form of treatment was a long one. The opportunity was taken of instructing male patients regarding the nature of the disease they were suffering from and of appealing to them to avoid infecting others. Many men, it would seem, acted on this advice, but the result was strangely one-sided. In other infectious diseases, when precautions against infection are taken, benefit is received by all alike. Syphilis, however, is peculiar, as it spreads from one sex to the other, and if one sex only adopts measures to avoid spreading infection the whole benefit of these precautions is received by persons of the opposite sex alone. It is thus that we account for the continuous fall of female deaths from general paralysis from 1907 to 1918, while the deaths of males remained stationary, or even tended to rise. There was a further fall of 33 per cent. in the

number of female deaths from general paralysis in 1919-20, as compared with the two previous years. This corresponds exactly with the fall in the deaths of males in time and proportion, but it was not directly due to treatment by salvarsan as was the case with males. It may, however, be traced to the employment of a rapid method of curing syphilis, with the result that the infectious stage of the disease in males was cut short by salvarsan, and fewer women became infected.

These observations teach us two lessons. The first, the success of modern scientific methods in preventing the most terrible malady to which man is subject. The money spent on clinics for the treatment of venereal diseases will in a few years be amply repaid. The other lesson is the effect of educational propaganda and publicity. I attribute the whole fall in the number of deaths from general paralysis among females up to the year 1919 to the instruction given to infected males. I believe also that those who have mainly benefited by the knowledge thus imparted have been the innocent wives of the less educated classes. Among these classes the proportion of women to men suffering from general paralysis is about 1 to every 4, but it may be as high as 1 to every 3. Among patients of the richer and better educated classes the proportion is very different: at Craig House there has been only one lady admitted suffering from general paralysis during the last twenty-four years, as compared with 73 men.

#### Prevention of Senile Insanity.

As to measures for the prevention of insanity during senility, Professor Robertson continued, we are guided by the knowledge that the later in life insanity begins the less important is the factor of hereditary predisposition in its causation; and that, in all forms of insanity occurring during senility, the influence of the body, if not paramount, predominates. For the prevention of insanity during senility we must begin to interest ourselves in bodily hygiene at a much earlier period. The diseases of old age are usually insidious in origin and gradual in development, and their seeds have been sown in middle life or even earlier. Syphilis and chronic alcoholism, for example, may not lead to any form of insanity in the early or middle periods of life, but owing to a progressive degeneration of the blood vessels of the brain and to a general lowering of the vitality, they may induce premature and marked senility and be the essential agents in the causation of insanity late in life. Prevention is then too late. Without doubt preparation for a healthy old age by careful living during the middle period of life is the best insurance against senile insanity. The measures employed to prolong life by increasing the number of the aged in proportion to the rest of the population, increase the total amount of insanity, for senility is the insanity-producing period of life. If this be associated with later marriage, a falling birth rate, and emigration of the young and fit, so that there is a proportionate diminution of the non-insanity-producing period of life, then in spite of all the efforts of mental and physical hygiene—indeed, partly on account of these efforts—the amount of insanity in proportion to the total population must show a marked increase. These statistical fallacies have to be eliminated before the relative amount of insanity from year to year, or in different areas, can be compared with accuracy. The alarmist, naturally, does not trouble to do this.

#### Is Insanity on the Increase?

Professor Robertson then turned to the question Is insanity on the increase? After pointing out that nations seem to pass through periodic phases in which fears arise that among them the occurrence of insanity is on the increase, he said that so far as can be judged the outlook in this country at the present time is distinctly favourable. In Scotland the total number of insane persons has fallen from 390 per 100,000 in the first quinquennium of the last fifteen years to 369 in the last; and the number of insane persons registered annually for the first time has fallen from 2,828 in the first quinquennium to 2,731 in the last, although the population has increased in number.

### Conclusion.

In conclusion, said Professor Robertson, it must be apparent to everyone that the problem of preventing mental disorder is not a simple one. The analogous problem is that of the prevention of tuberculosis, with which it has so many points in common, and from the campaign for its prevention much can be learned. The possible causes of mental derangement are legion, and the possible combination of these, in individual cases, beyond counting. It is clear that when sickness of mind threatens or occurs, mental health cannot be regained by any royal road. The claims of the individual sufferer are in the first place paramount and must be studied. Every case of threatened breakdown presents a unique problem. It may have features in common with others; it certainly will present features peculiar to itself. Intensive study, therefore, of individual cases, so as to disclose these causative factors, is the primary duty of the psychiatrist. If that duty be not discharged, treatment will be confined to a few rule-of-thumb precepts, and its results will be disappointing. Secondly, what can be done in a more general way is well illustrated in the case of general paralysis. By disseminating, as widely as possible, information as to its mode of attack and the methods of prevention, a real contribution has been made to the mental hygiene of the community. Encouraged by that success, let us see to it that our knowledge of the origin and development of other disabling conditions is effectively applied wherever it is needed. In the opening up of these preventive channels a great responsibility rests on practising psychiatrists. It is futile to lament that those of unstable equilibrium turn elsewhere for help—to the quack, to the charlatan, to the barren ritual of the latest cult. The blame for this state of affairs must be shared by the psychiatrist. Far too long has he sulked in his cave; now he must come out into the market-place and offer his wares to all who need them. He must not confine his interests to his duties in the mental hospital. He must co-operate with the general practitioner and get into touch with the outer world through the agency of out-patient clinics. An expert body of psychiatrists, trained in every device of medicine and psychology, and diligently applying themselves to the clamant needs of their generation, might avert much needless suffering on the part of those in mental difficulties or about to be overwhelmed. Let none be daunted by the magnitude of the enterprise that is envisaged, but rather find in it an incentive to continued and combined effort, and the hope of a greater reward.

## DARK-GROUND ILLUMINATION OF TISSUE CELLS CULTIVATED "IN VITRO."

BY

T. S. P. STRANGEWAYS, M.A., M.R.C.S., L.R.C.P.,  
LECTURER IN SPECIAL PATHOLOGY, CAMBRIDGE UNIVERSITY;  
DIRECTOR, CAMBRIDGE RESEARCH HOSPITAL.

AND

R. G. CANTI, M.D.,

LECTURER IN BACTERIOLOGY, ST. BARTHOLOMEW'S HOSPITAL, LONDON.  
(From the Laboratories of the Research Hospital, Cambridge.)

THE cultivation of animal tissues *in vitro* is now a recognized method of research. When a fragment of tissue is cultivated upon a cover-slip in suitable medium a zone of cells grows out around the edge of the fragment. Many of these cells become adherent to the surface of the cover-slip and wander over it by amoeboid movement, pushing their way along the plane between the glass and plasma jelly. Such cells are very suitable for microscopical observation, and studies of the cells carried out under direct illumination have already been reported.<sup>1</sup> The thin film of growing cells is peculiarly suitable for observation by dark-ground illumination, and by this method beautiful and instructive pictures of the living vegetative cells can be obtained. The technique for this examination requires considerable experience and care, but presents no great difficulty to workers familiar with critical microscopic technique.

<sup>1</sup> A demonstration given to the Section of Pathology and Bacteriology of the Annual Meeting at Nottingham on Friday, July 23rd, 1925.

The following description of the apparatus and methods used for the examination and study of tissue cells by dark-ground illumination may be useful to workers not familiar with this method of microscopic examination.

The cultures must be put up on thin glass slides not more than 0.6 mm. in thickness, and the thickness of the whole preparation must not exceed 0.9 mm.

The tissue may be cultivated in plasma or in plasma and embryo extract on a cover-slip sealed over a hollow-ground slide, and just before examination the cover-slip can be removed and transferred to a thin glass slide on which a drop of Tyrode or other suitable saline solution has been placed; the cover-slip is then sealed down with paraffin wax to prevent evaporation.

A better method, however, is to cultivate the tissues directly on the thin glass slide. By this means it is possible to use cultures growing in fluid as well as semi-solid media. Care must be taken not to press upon the cover-slip while handling the cultures as pressure may damage the growing cells. Too violent excursions of the oil-immersion objective will also cause damage.

The microscope we have used is a Zeiss microphotographic stand with mechanical stage and sliding objective carriers. Before any attempt is made to use the dark-ground condenser the objectives must be carefully centred. A triple nosepiece is to be avoided, as the three portions are seldom in exact optical centre and cannot be adjusted. The sliding carriers on the other hand, are readily adjusted, and with a little experience give no more trouble than a triple nosepiece. Each objective must be centred and kept on its own carrier.

FIG. 1.—Diagrammatic drawing of lantern. A, Metal shield bent at right angles holding a pointillite lamp; the whole slides on B, a steel rod to which it is fixed with a thumbscrew C. This arrangement allows the lamp to be moved as required for centring with the lens D. The lens carrier slides in a sleeve, E, fixed to the front of the body of the box F. The top and back of the box are open and the bottom is made of a cast brass plate, G, to which is fixed the steel rod which carries the lamp-holder. This plate is pivoted at its centre and rides on a similar cast brass plate, movement laterally, being obtained by the thumbscrew H. The lower plate is in turn pivoted at its forward end to a bar, J, fixed to the table, so that the whole lantern can be tilted up or down by the thumbscrew K.

The following instructions for centring the objective may be useful to those not accustomed to critical work.

1. Swing out the lower substage diaphragm, and the Abbé condenser, leaving the upper substage diaphragm in position; close this as far as possible.
2. Place the 2/3 inch objective with its sliding carrier in position and, using diffuse light, focus on to the aperture of the diaphragm.
3. Centre the 2/3 inch objective to the aperture of the diaphragm, using the key.
4. Replace the Abbé condenser, and place a centring slide on the microscope stage.
5. Focus on to the cross-line of the centring slide with the 2/3 inch objective and place the cross-line exactly in the centre of the field.
6. Remove the 2/3 inch objective and replace by the 1/8 inch, and later by the 1/12 inch, each on its own carrier. Using the key, centre these lenses to the cross-line.

All the lenses are now centred to the aperture of the upper substage diaphragm and hence to each other.

The source of light used for illuminating the object is a pointolite of 100-c.p. This is fixed in a special lantern constructed of metal plate, made by Maslin. In the front is a Zeiss aplanatic condensing lens (Model Ic.) with iris diaphragm. The lamp is capable of being centred to this lens, and the whole lantern with the lamp can be tilted either vertically or horizontally as one unit. Fig. 1 will make the construction of this lantern clear.

The examination of the cultures is made in an incubator regulated by a Hearson thermostat and containing the microscope (Fig. 2).

FIG. 2.—Incubator arranged for use.

The incubator consists essentially of a wooden box 20 inches long by 9 inches wide by 12 inches high.

The microscope is placed inside close to the right-hand end in order that a camera lucida attachment with drawing-board may be employed. The tube of the microscope projects through a hole 2 inches in diameter in the top of the box. This hole has its centre  $3\frac{1}{2}$  inches from the front and 3 inches from the right-hand side. To the left of this opening a square is cut out of the top of the box and fitted with a sheet of glass through which a view may be obtained of the interior. This square is fitted with a hinged wooden door. In the front of the box opposite the mirror of the microscope is a window, fitted with glass, through which the light is admitted to the microscope from the lantern.

The back of the box is divided vertically into three equal portions, the left and right being closed with a door, hinged at the bottom, giving access to the heating elements and the microscope respectively. The middle partition is open, and is fitted with a velvet sleeve through which the microscope is manipulated.

The heating elements consist of two 16-c.p. carbon filament lamps run from the mains, one of which is kept permanently alight and the other is connected in series with a Hearson's capsule thermostat regulated at  $38^{\circ}\text{C}$ . The connexions required are shown in Fig. 3.

FIG. 3.—Heating elements showing connexions.

The capsule is protected from the direct radiation of the lamps by means of a small cardboard tray suspended beneath it.

The mirror in the model of the microscope employed is ordinarily attached to the substage condenser, so that it moves with it. When a focused source of light is used this form of apparatus is inadmissible, and the mirror is

therefore removed from the microscope and attached to the floor of the box on a sliding base. The microscope is placed so that it stands vertically over the mirror, and is kept in position by a horseshoe-shaped plate of lead 1 inch thick, cast so that it fits the base of the microscope stand (Fig. 4).

This arrangement keeps the microscope rigidly in position during the various manipulations required, and at the same time allows the whole instrument to be moved at will and its position adjusted as required.

FIG. 4.—Mirror and lead plate to fit base of microscope stand.

The dark-ground condenser is made by Swift with numerical aperture 0.95. The objectives used are  $1/8$  inch oil immersion by Swift with numerical aperture 0.95, and a  $1/12$  inch objective by Zeiss suitably stopped. The selection of the objectives is of considerable importance. Most of the stops supplied to bring down numerical aperture of the ordinary  $1/12$  inch do not fit closely to the back of the lens, and thus perfect definition cannot be obtained. The authors advise an objective of the correct numerical aperture. The usual eyepieces are used, and also an X1 Telaugic by Swift.

The apparatus is assembled as follows. The pointolite lamp is first adjusted in the lantern so that the centre of the lens is in alignment with the point of light of the lamp. To ensure this the light is focused through the lens on to a strip of white paper about 4 feet away, and the bright image of the glowing tungsten ball of the lamp is thus readily obtained. The lamp is now moved vertically and horizontally as required until the image of the tungsten ball is clearly seen surrounded on all sides by an equal halo of coloured light. It will be found that as the lamp is moved the halo moves to one or the other side of the circle of light, and a truly centred beam is only obtained when the coloured halo is seen encircling the light evenly. The lamp is now fixed in front of the microscope incubator and focused on the mirror at such a distance that the size of the tungsten ball on the mirror is not larger than 10 mm. in diameter. This is ensured by pasting upon the concave surface of the mirror a piece of paper with a scale marked upon it as shown in Fig. 5. The mirror is now turned round so that the plain surface receives the light. The microscope, with all the lenses removed, is now adjusted so that the light passes directly upwards through the draw-tube. This is a detail of great importance and requires practice. The iris diaphragm of the substage is placed in position. The beam of light is now thrown upon the ceiling through the draw-tube, and by alternately opening and closing the iris diaphragm of the substage and that in front of the condensing lens of the lantern it is possible to judge if the beam of light from the lantern is passing centrally through the draw-tube; the two circles of light, which may be caused to increase or decrease in size by opening one or other of the iris diaphragms, must coincide exactly and the circle of illumination must show relatively sharp edges, blurring on one side or the other indicating that the beam of light is not central. When the light has once been centred, the lantern, the microscope, and the mirror must on no account be moved again or shaken. If accidental movement occurs during subsequent manipulations the whole process of centring must be repeated. A piece of white paper is not inserted on the top of the substage about  $3/4$  inch below the opening in the microscope stage. The light is carefully focused on this sheet of paper by moving the condensing lens on the lantern in or out, care being taken

that the lantern is not moved while adjusting the lens. The image of the tungsten ball on the paper should not exceed 10 mm. in diameter. The paper is now removed and the iris diaphragm of the substage swung out and the dark-ground condenser gently placed into position on the substage. Great care must be taken not to touch the mirror or to move the microscope while this manipulation is being carried out. The condenser is then racked up to the level of the stage. The 2/3 inch objective, which has already been centred, is put in position and a No. 1 eyepiece inserted into the draw-tube. The surface of the condenser is brought into focus and the rings engraved on the surface are carefully centred by means of the centring screws of the carrier of the condenser. The apparatus is now ready for use.

To examine the cultures, switch on the heating bulbs of the microscope incubator and allow the temperature to become steady at 38° C., if this has not already been done. Open fully the iris diaphragm of the lantern and note again that the dark-ground condenser is centred correctly. Rack down the condenser about 1/4 inch. Take the culture to be examined and on the under side of the glass slide place a large drop of cedarwood oil. Place the slide in position on the stage of the microscope and rack up the condenser until the oil on the slide touches the top of the condenser. Air bubbles must be avoided. Focus the central fragment of tissue in the culture and clamp slide to the stage. Rack up the condenser; a dark circle gradually appears in the centre of the field, which becomes smaller as the tungsten ball is raised, and suddenly a very bright image of the tungsten light is seen focused on the fragment. This bright image should be exactly in the centre of the field. When the 2/3 inch objective is removed carefully and replaced either with the 1/8 inch or the 1/12 inch oil immersion as required. The iris diaphragm of the lantern is closed to an opening of about 1/8 inch in diameter and the oiled objective brought down and focused on the central fragment. The condenser is now racked slowly up, and if the centring light will appear to one side of the field, and a slight adjustment of the objective with the key of the carrier is permissible in order to bring it to the true centre. If, however, the area of light is quite outside the field then the apparatus must be again set from the beginning. If a worker is warned that it requires considerable practice to obtain this true centring, but unless the necessary skill is acquired good results cannot be expected. When the light is correctly centred the culture is moved by the mechanical stage so that cells at the edge of the central fragment which are in single layer are brought into the field. To obtain good definition the objective and condenser are carefully focused and the light of the lantern is adjusted by the iris diaphragm of the lens. A mercury green line filter placed in front of the lantern renders the light approximately monochromatic and increases the sharpness of the image; in addition, light of this colour is useful in preventing eye-strain.

It should be noted here that the dark-ground method of illumination shows up one thing only, and that is the interface between two surfaces of different refractive index. When each of the substances on either side of the interface is clear then the interface is shown as a white line with blackness on either side of it. If, however, one of these substances should contain, for example, particles of a different refractive index, then this substance will appear annular or cloudy, according to the size of the particles. Bright light will show up as a cloud the presence of particles which, owing to their fineness, a less bright light would leave as a complete blackness.

Cultures of tissue cells of about eighteen to twenty-four hours' incubation which are growing well should be selected for examination. In such cultures the outlines, internal structures, and complex internal movements of the vegetative cells are clearly shown. The vegetative cells when growing upon the cover-slip usually have a feather-like outline. The cytoplasm is clear and in it the various cell structures are seen embedded; the nucleus appears as a clear or rounded body with a sharp outline and contains

one or two distinct, slightly opaque bodies—the nucleoli. In the cytoplasm the most prominent objects are small globules of fat which are present in varying numbers in practically all cells cultivated *in vitro*. These fat globules are seen as very bright refractile spheres. The fat globules vary much in size and become larger and more numerous as the culture grows older. A varying number of fine somewhat refractile granules are also seen; these are quite small and not so bright as the small fat globules. The mitochondria are clearly seen in the cytoplasm as fine threads which vary greatly in length. The centrosphere shows as an obscure area on one side of the nucleus. The cell undergoing mitosis is not well shown by dark-ground illumination, as such cells become spherical in shape and thus are not so suitable for critical study as the flattened vegetative cell. The fat globules, however, and some of the small granules and some of the mitochondria can usually be made out lying round the clear spindle-shaped area of protoplasm, in which can be seen indications of the chromosomes, especially when the cell is at metaphase.

The structures described above can be well seen in cultures examined under dark-ground illumination at room temperature without the use of a microscope incubator, but the fascinating movements of the cell and its structures do not take place under these conditions.

## Memoranda: MEDICAL, SURGICAL, OBSTETRICAL.

### A METHOD OF REDUCING CERTAIN DISLOCATIONS OF THE SHOULDER.

I WAS recently called to a colliery ambulance room to see an old man—an underground haulier. He was sitting on a bench with the right arm hanging down by his side, and he was apparently in great pain.

Half an hour before the patient had been pushed by his horse and had fallen against the side, receiving a sharp blow on the upper and back part of the right shoulder-joint. He had "felt his arm go out" and had "felt sick." He had a very obvious subcoracoid dislocation of his right shoulder-joint. He had never before had a dislocation.

Stripping him of his shirt, I tried Miller's method of reduction with countertraction by means of a towel round the chest for some time, but without success. I then carried out Kocher's manoeuvres, but these also failed to effect reduction. I resorted, in turn, to hyperabduction with traction, to leverage with the patient's arm round my waist, and to the heel in axilla method. These were all unavailing. I was about to administer an anaesthetic when it occurred to me to try a simple manipulation of the head of the humerus, which I could feel medial to the biceps and coraco-brachialis muscles. This was immediately successful—despite the fact that the patient was not faint, nor were the muscles relaxed. Further, the successful method caused the patient no pain at all. The plan was as follows (for right shoulder):

1. With the patient recumbent, the right arm is grasped at the elbow and lifted forward and upward until the patient's arm is almost extended above his head. This places the arm in position for movement 2, and relaxes the biceps, coraco-brachialis, and deltoid muscles.
2. With the patient's arm still raised, pressure is applied to the elbow as if trying to make the head of the humerus touch the table. The line of force is thus vertical, from the elbow through the shaft and head of the humerus. At the same time the operator's left fingers are spread out on the back of the patient's right shoulder, while the thumb in front presses the head of the humerus downwards and so helps it to travel back under the muscles whence it came. By this manoeuvre the head of the bone passes back round the neck of the scapula under the below the glenoid cavity. The dislocation is thus converted into a subglenoid one.
3. The patient's arm is now brought down parallel with the trunk.
4. Finally, with the operator's clenched left fist in the axilla to act as a fulcrum, the patient's elbow is now approximated to the side—when the head of the bone will re-enter the capsule and will be felt—and heard—to slip over the labrum glenoidale into position.

*After-Treatment.*—In this it is important that the elbow on the injured side be well supported, thus preventing the head of the humerus from pressing on the damaged lower part of the capsule.

Pontycymmer, Glam.

VERNON NEWTON, M.R.C.S.Eng.

## THE GOLD TREATMENT OF TUBERCULOSIS.

## SECOND REPORT BY THE MEDICAL RESEARCH COUNCIL.\*

This second report deals almost entirely with clinical experience. It does not attempt a review of the laboratory evidence on what is at the root of the whole inquiry—namely, the action of sanocrysin in arresting the spread of tuberculosis implanted experimentally into animals.

## CLINICAL OBSERVATIONS.

The results are given briefly for each separate clinical centre at which the observations were made. For convenience of reference the after-history of individual patients who were given by serial numbers in the first report† is here described under the same serial numbers. No new reference numbers are given for fresh cases described in the present report.

ST. BARTHOLOMEW'S HOSPITAL (PROFESSOR F. R. FRASER AND  
DR. C. F. HARRIS).

Eleven cases of pulmonary tuberculosis have been treated or are undergoing the treatment. Two cases of abdominal tuberculosis were treated and one case of lymphatic leukaemia was studied as a control. The cases of pulmonary tuberculosis were all of a more chronic type than those in which the best results are reported from Denmark. One death occurred after a few doses of sanocrysin, which were given only because a fatal issue seemed inevitable. Severe reactions were experienced with large doses, but later it was found that with smaller initial doses at longer intervals the treatment was well tolerated. No striking results have been obtained, but the unexpected improvement in certain cases suggests that sanocrysin may be of service in the early cases of pulmonary tuberculosis or in the fresh spread in more chronic cases. The general impression has been formed that the method of treatment deserves further investigation.

## LONDON HOSPITAL (PROFESSOR ARTHUR ELLIS).

Since the publication of the last report only one new case of pulmonary tuberculosis has been treated. This patient, whose condition was desperate at the time treatment was commenced, improved to a very remarkable extent. The patient had been under observation in hospital for nearly a year and was going very rapidly downhill with hectic temperature, repeated haemoptysis, and severe pleural pain. At his own insistence a course of sanocrysin injections was given. No severe reactions occurred and improvement was rapid and continuous. He became afebrile, pain, cough, and haemoptysis disappeared, his sputum diminished from four ounces daily to slight morning sputum only. He was discharged to a sanatorium and when last heard from some weeks ago was doing well.

The after-histories of the cases detailed in the first report have been as follows:

*Case 1.*—Has been in a sanatorium and is now back at home. His general condition is much the same as on discharge, but the breath is now definitely fetid and the moist sounds at the right base are much more numerous. The cough and sputum have both increased. There are no tubercle bacilli in the sputum.

*Case 2.*—Gradually failed, and died in his home in January, 1926. No post-mortem examination was obtained.

*Case 3.*—Downward progress continued. He died early in June, 1925, five months after the last injection of sanocrysin. Specimens of various viscera were obtained post mortem and sent to an analytical chemist for analysis for gold. The kidney, liver, and colon contained no trace, but in a portion of the lower lobe of the left lung a definite trace of gold was detected, estimated roughly at 3 mg. per 100 grams of lung tissue. The total gold salt used in this case was only 1.5 grams.

*Case 4.*—Recovery from the exfoliative dermatitis eventually occurred. Coincident with this, the exacerbation of the tuberculous process gradually subsided and the patient again became afebrile. She is now able to be up and about, but the physical signs are more extensive and her general condition worse than before treatment was given. It is some three months since she was last seen.

*Case 7 (Control).*—This patient was a case of Hodgkin's disease treated with sanocrysin as a control. The patient died in January, 1926. No post-mortem examination was obtained.

Professor Ellis considers that the value of the serum is doubtful. He suggests that his bad results may have been due in part to serum. All the cases that did badly had very severe serum sickness. It was in the period of resulting prostration that exacerbation of the tuberculous process was particularly manifest.

## ST. MARY'S HOSPITAL (PROFESSOR F. LANGMEAD).

No new cases are reported. With regard to the original cases: *Case 9.*—Convalescence was satisfactory. The patient went to Ventnor for six months, where tubercle bacilli were present in the

sputum at first. Her health is now fairly good. The sputum has been free from tubercle bacilli for some time, and radiographs show that there has been no spread of disease.

*Case 10.*—Satisfactory convalescence. At work as a carman since August, 1925, and no tubercle bacilli in sputum. A similar recovery had occurred previously, and before sanocrysin treatment, when the patient had been rested in a sanatorium.

ST. THOMAS'S HOSPITAL (PROFESSOR H. MACLEAN AND  
DR. G. T. HEBERT).

Ten new cases have been treated with considerable, though it may prove to be only temporary, improvement.

Out of the five original cases which were chosen as being of a mild type, two have relapsed decisively. The after-history of all the original cases is as follows:

*Case 11.*—Has kept well; no evidence of active tuberculosis, but is under treatment for pityriasis rosea.

*Case 12.*—Went to a sanatorium for three months, until June, 1925; tubercle bacilli in sputum at that time. He was in good health three months later but not at work; then married and moved out of London, leaving no address.

*Case 13.*—Went to a sanatorium for three months, until July 8th, 1925; apyrexial, but tubercle bacilli in sputum at that time. He worked in the country as a grocer's assistant till December, 1925, when symptoms of active disease reappeared. In January, 1926, there was infiltration of both lungs, and in March, 1926, he was admitted to the Lambeth Hospital.

*Case 14.*—Went to a sanatorium for three months, until July, 1925. No further definite symptoms of tuberculosis. The patient is now at work.

*Case 15.*—Lived in the country during the summer of 1925. In September, 1925, was not looking well, but no tubercle bacilli were present in the sputum. Patient had pleurisy of the left side in December, 1925, followed by symptoms of active pulmonary tuberculosis. Admitted to a sanatorium in February, 1926.

## UNIVERSITY COLLEGE HOSPITAL (PROFESSOR T. R. ELLIOTT).

Twelve cases of tuberculosis have been treated, including the four described in the first report. Three were of glandular or osseous infection, and gave no special information. There were seven patients with pulmonary tuberculosis.

*Case 16.*—In the first report it was concluded that the girl had been made worse by the treatment. After discharge from hospital she remained at home in a poor environment. But she is now well and back at work. There are no tubercle bacilli in the sputum, and the disease appears to be completely arrested; an unexpectedly good recovery in view of her originally poor physique.

*Case 18.*—The patient returned to work soon after discharge from hospital and remains well.

*Case 19.*—The boy went to work with very long hours in a factory last autumn. His health broke down and he was readmitted to hospital. There appeared to be more extensive fibrosis in the lungs, but there were no tubercle bacilli in the sputum. He recovered quickly and was then sent to the country.

One new case of pulmonary tuberculosis developed very serious jaundice, with clay-coloured stools, after two doses of 0.5 and 1 gram respectively. Recovery from the hepatitis was slow and treatment was therefore discontinued. Such toxic jaundice appears to be rare in Danish experience. A similar but fatal case was described (Case 8 from St. Mary's Hospital) in the first report.

Another patient with extensive caseous lesions in the left lung and only two months' history improved with great rapidity under treatment. The fever ceased after two severe rash reactions, and ultimately the tubercle bacilli disappeared from the sputum. Three months later a relapse occurred at a sanatorium during December. The patient was readmitted to hospital, with further spread in the lungs and tuberculous laryngitis. A second course of sanocrysin failed to evoke a rash or high pyrexia. The patient is still under treatment and appears to be improving only slightly.

One control case was tried, a woman aged 25, with prolonged fever ranging daily from 99° to 101°, and high eosinophilia—60 per cent., of unknown cause. Three injections of 0.5 gram each were given; no rash resulted nor any obvious temperature change.

The best results in tuberculous infections seem to have been obtained when the patient reacted strongly with fever and a rash. Professor Elliott concludes that the treatment is definitely beneficial in early cases without extensive fibrosis, though it is rarely capable of effecting a rapid and complete arrest of tuberculous disease.<sup>2</sup>

## GUY'S HOSPITAL (DR. G. MARSHALL).

Sanocrysin had not been used at this centre at the time of the first report. During the last year eight cases of pulmonary tuberculosis have received treatment. All these cases had extensive pulmonary disease and were of some length of duration. Three cases showed apparent arrest, two cases improved, while the remaining three cases were unimproved. In no instance was disease extended by the treatment. The improvement resulted after other modes of treatment, such as rest and sanatorium, were tried and failed. Severe reactions with exanthem and albuminuria have been observed, although small doses were employed. One case of infective endocarditis, in which the spleen diminished in size and became impalpable, ceased treatment after eleven doses.

\* The first report was published in the BRITISH MEDICAL JOURNAL on April 18th, 1925 (p. 735).

In addition, provocative diagnostic doses of sanocrysin have been given to three patients. It is considered that sanocrysin has a beneficial effect when used with discretion and is likely to become a part of the routine treatment in selected cases of pulmonary tuberculosis.

# BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (DR. L. S. T. BURRELL).

At this centre also observations had not been commenced at the date of the first report a year ago. Twenty cases were selected for treatment, as being patients who were getting worse or had failed to improve after other methods had been tried. These form the large group of fibrotic and fibro-calcareous cases, slowly progressive with frequent relapses and periods of improvement. Time will show whether or not the progress of disease can be checked in these cases by sanocrysin, and in this report it is only the immediate result that can be shown.

In the first 5 cases in the series artificial pneumothorax had been induced with very good initial results. In each case, however, there had been a relapse with return of sputum containing tubercle bacilli. After a short period of treatment with sanocrysin one patient was slightly worse. The other four improved, two of them losing the tubercle bacilli from the sputum. The next 8 cases, Nos. 6 to 13, were of the fibro-calcareous type. In all, the sputum containing tubercle bacilli was present. After sanocrysin the number of tubercle bacilli in the sputum was reduced in every case and in four they disappeared altogether, though they reappeared in two of these. In another case, No. 14, there was long-standing disease complicated by a chronic pleural effusion, which was converted into a hydro-pneumothorax. Sanocrysin was given in order to control the disease in the other lung, but it had no apparent result, either good or bad. No. 15 was one of spontaneous pneumothorax, and again the sanocrysin was given in an attempt to improve the condition of the other lung. The patient, however, became worse.

In the final 5 cases there was bilateral disease; the worse lung was treated by artificial pneumothorax and sanocrysin was also given in the hope that it would have a good effect on the disease in the other lung. Of these 5 cases the tubercle bacilli disappeared from the sputum in 4 (though in one they reappeared) and in the other they were much reduced in number. This result, however, was probably due largely to the pneumothorax, and in one case (No. 16) the tubercle bacilli disappeared after the pneumothorax had been induced but before the sanocrysin was started.

The sanocrysin was given intravenously and the initial dose was 0.25 gram. This was followed a few days or a week later by 0.5 gram, then 0.75, and finally 1 gram. This was the maximum dose given, and was repeated weekly. It was noticed that in many cases no reaction occurred until a dose of 0.75 or 1 gram was reached, and that the reaction got less on subsequent injections. In two cases small doses (0.1 gram) were given daily for a week, and then this course repeated after a week's interval. This method had no effect in one case, and in the other it produced slight albuminuria, pains in the limbs, and disappearance of tubercle bacilli from the sputum. This method of giving frequent small doses might possibly be of advantage in acute cases. Taking the 20 cases as a whole, 2 became worse and 18 improved or remained unchanged. In 10 cases tubercle bacilli disappeared from the sputum, although in 3 of these they reappeared. In 5 cases there was no reaction after the injections. Rigors occurred in 9 cases, and a slight evening rise in temperature. A long febrile reaction was also noted after some of the injections. In 5 erythematous rash occurred in 4 cases. Vomiting a few hours after the injection in 9 cases. Pain in the limbs was present in 4 cases. Albuminuria was noted in 3 cases only and was very slight and transient. One patient complained of a metallic taste in the mouth, and small blisters appeared on the mucous membrane of the mouth.

## WARWICKSHIRE KING EDWARD VII MEMORIAL SANATORIUM, WARWICK (DR. F. R. G. HEAF).

Twenty patients suffering from pulmonary tuberculosis (all stages, with tubercle bacilli present in the sputum) have been treated with sanocrysin, and 6 are still under treatment. Of the 20 patients, 2 left before the course of treatment was completed, and in 2 cases treatment was stopped owing to the advanced state of the disease. Of the 16 remaining cases, 10 were regarded as quiescent at the termination of treatment, tubercle bacilli being absent from the sputum and x-ray evidence and physical examination indicating marked improvement; 1 was improved but tubercle bacilli were still present; 2 showed no alteration, and with artificial pneumothorax treatment, and the progress of a recent lesion on the side opposite to the collapsed lung was arrested.

Dr. Heaf hopes to be able to report on the after-history of the patients at the expiration of one year. He concludes that sanocrysin arrests the early progressive lesion but has little or no effect upon lesions associated with fibrosis.

## WALES (PROFESSOR S. LYLE CUMMINS).

Sanocrysin has been tried at three centres in Wales under the general supervision of Professor S. L. Cummins. In all, 16 cases have been fully treated, as follows:  
At Glan Ely Hospital, Cardiff: Professor Cummins, 6 cases;  
Dr. A. Brownlee, 1 case;  
At Cymia Hospital, Neath: Dr. N. Tattersall, 6 cases;  
At South Wales Sanatorium, Talgarth: Dr. H. E. Watson, 3 cases.

Details of the individual cases and their results are given elsewhere by Professor Cummins and Dr. Tattersall. The after-history of the cases quoted in the original report a year ago is as follows:

*Case 21.*—The patient was sent to a sanatorium. Sputum was negative for a time, but in July became positive. Two more doses, 0.5 gram and 1 gram, were given. Tubercle bacilli disappeared from the sputum and the patient regained weight. He now has persistent albuminuria.

*Case 22.*—The patient returned to work at a colliery in April, 1925. In July tubercle bacilli appeared again in the sputum, and he was later admitted to hospital. A second course of 2.25 grams was given in November. The patient has regained weight and is now capable of light graded work.

Two cases of extensive and obviously grave pulmonary tuberculosis, aged 14 and 15 respectively, died two or three months after sanocrysin treatment, which did not appear to have influenced the illness in any markedly unfavourable way.

One of Dr. Watson's cases developed exfoliative dermatitis, presumably from metallic poisoning, after 6.25 grams. Professor Cummins' patients had all given fairly good results. Cases, had four favourable results. "There was dramatic and rapid improvement in each of them after a short course of sanocrysin. The tubercle bacilli disappeared from the sputum and the weight after treatment got back to or outstripped the highest known weight. This favourable change, though not persistent, was maintained for several months after the course of treatment." Professor Cummins concludes that sanocrysin, judiciously used, is a valuable means for raising the less advanced type of "hospital" case up to a "sanatorium" level, and perhaps for the actual cure of some cases of a more favourable clinical type.

## — EDINBURGH ROYAL INFIRMARY (PROFESSOR SIR ROBERT PHILIP AND PROFESSOR D. MURRAY LYON).

Twenty-two cases of tuberculosis have been treated by means of sanocrysin. Undoubted cases of tuberculosis were selected who had already benefited by institutional treatment. All cases were afebrile. Seventeen were examples of pulmonary tuberculosis with localized nodules in the sputum. The lesions ranged from slight tubercle bacilli in the sputum to extensive cavity formation or marked fibrosis. The series examined also included 2 cases of tuberculosis of the glands, 1 of renal tuberculosis, and 2 of lupus. Other therapeutic measures were discontinued during the trial of sanocrysin. Eight patients had previously had more or less prolonged treatment with tuberculin by percutaneous method.

The patients received from two to ten injections of sanocrysin, the most usual number being six. The quantities of sanocrysin administered have varied from 1.5 to 10 grams. In all cases the initial dose was 0.5 gram, and subsequent injections have usually been 1 gram. Antituberculous serum was given in 10 of the cases and in small quantities only (doses of 20 to 40 c.c.m.), but its use was not encouraging.

Considering first the 5 cases of non-pulmonary tuberculosis, the renal case was unimproved. One case of tuberculosis of the glands was improved, the glands becoming more discrete and finely smaller; in the other case the treatment had to be discontinued owing to severe local inflammation. The 2 cases of lupus after each injection of sanocrysin exhibited a considerable congestion in and around the affected area. Later the scales practically disappeared and the centres of the lesions became pale as if cicatrization had increased. The margins, however, remained red and raised in nodules. When last seen, ten months after the beginning of treatment, both cases had relapsed, the lupus areas appearing active and heavily encrusted.

Of the 17 cases of pulmonary tuberculosis the treatment had to be discontinued in 7 cases—in 3 because of the severity of the reactions and in 4 others on account of the discomfort and distress experienced by the patients. Of the 10 cases that underwent the full course, 7 ultimately showed decided improvement when examined from five to ten months after termination of treatment. One, who was apparently doing well, subsequently had several attacks of haemoptysis and died.

In studying the effects of the sanocrysin treatment of tuberculosis, the Edinburgh workers state that the principal questions to be answered are: (1) Whether sanocrysin possesses any specific action against tuberculous tissues. (2) Whether its employment has benefited the patients subjected to it. (3) Whether the present method of administration is the most suitable.

(1) It is observed that the reactions which follow the administration of sanocrysin might arise in different ways. (a) the drug, unchanged or chemically altered, may act on the tissues directly; (b) as a result of a selective action of the gold on tuberculous tissues and organisms, specific toxins might be liberated. The resultant reactions might be termed "gold" effects and "tuberculous" effects respectively. The evidence suggests that the focal eruptions, the pyrexia and the gastric symptoms, especially vomiting, which the authors noted accompanied the earlier doses of sanocrysin in a course, may be regarded as "tuberculous" effects. On the other hand, the albuminuria which occurs late in the course and in association with de-quarantine skin lesions and many of the alimentary symptoms (stomatitis and diarrhoea), appears to be a "gold" effect due to irritation accompanying the accumulation of the metal in the renal cells. The gold salt, therefore, appears to produce two types of effect in the body: the "specific" action on tuberculous areas which is immediate, and the cumulative poisoning seen in the excretory organs. The authors add that two questions still remain unsolved—namely, the cause of the early decline of the "tuberculin" reactions, and

the reason for the failure of later doses of sanocrysin to evoke albuminuria.

(2) The immediate effects on the health of the patients have varied greatly. The majority have experienced more or less discomfort and some have suffered severely. The gastric symptoms and tendency to severe dermatitis, combined with the almost universal and often considerable loss of weight, make the treatment a matter not lightly to be undertaken in its present form. To avoid the risk of producing severe reactions it would appear desirable to aim at a smaller concentration of sanocrysin in the system, either by reducing the size of the dose, or by lengthening the interval between the doses, or by combining these suggestions. In several cases a striking reduction has occurred in the number of tubercle bacilli in the sputum. Negative films became more frequent in some patients, but in no instance did the bacilli permanently disappear from the sputum, and, as yet, no patient can be said to have had his disease arrested. Apart from the loss of weight produced no patient has been harmed by the course of treatment. The one death that occurred is not ascribed to the treatment, as it took place after the full course had been completed with apparent benefit at first resulting. Some degree of clinical improvement has been observed in the greater proportion of patients who underwent the full course. No dramatic change has occurred, but there has been in several instances a steady advance at a greater rate than might otherwise have been expected. This improvement has not in all cases been maintained; some of those who did best during the course have since retrogressed, while others who did not seem immediately benefited have since greatly improved.

(3) The authors conclude their report by some observations on the intramuscular administration of sanocrysin. They formed the impression that this method presented some advantages—for example, less albuminuria and less rapid loss of weight—and that further experience was likely to reveal ways of still further excluding the discomfort of the procedure.

#### PUBLIC HEALTH DEPARTMENT, EDINBURGH (DR. J. GUY).

Dr. Guy has treated 10 cases of pulmonary tuberculosis with sanocrysin. The first 6 were given small and gradually increasing doses; and the last 4 received large doses but not the full doses recommended by Professor Moellgaard. In the first 6 of the series sanocrysin did not appear to have any appreciable effect for good or ill. In the last 4 there appeared to be some slight improvement and lessening of the sputum. This, however, is a regular feature of sanatorium régime. Dr. Guy considers that so far there does not appear to be any marked curative effect from sanocrysin. He infers that the drug has some specific effect on the tuberculous lesion, as in the last 4 cases treated signs of increased moisture were commonly noted after the injection. He regards sanocrysin as worthy of further trial.

#### NORTHERN IRELAND (DR. A. TRIMBLE AND OTHERS).

A committee was constituted last year to supervise the trial in the Belfast area of sanocrysin as a method of treatment of tuberculosis. The reports from the three institutions selected for the test are thus summarized:

**Belfast Municipal Sanatorium (DR. PERCY WALKER).**—Six male patients treated. Each patient received seven injections, totalling 6.5 grams each. All these patients were suffering from pulmonary tuberculosis (Turban-Gerhardt: third stage). Result: 1 case appears to be arrested, 2 are definitely greatly improved, the sputum being now negative as regards tubercle bacilli, 2 are improved clinically but the sputum is still positive. One case shows no change. A second group of 3 patients is still undergoing treatment.

**Forster Green Hospital (DR. B. R. CLARKE).**—Twelve cases of pulmonary tuberculosis treated, 11 with tubercle bacilli in the sputum. Results: The sputum of 4 patients became negative; 4 patients had a diminished number of tubercle bacilli, and in 2 patients there was an actual increase of tubercle bacilli after treatment. Clinically 8 of the 12 patients showed improvement, the condition of 2 was unchanged, and 2 appeared to be worse as a result of the treatment. Five further cases are undergoing treatment.

**Royal Victoria Hospital (DR. S. I. TURKINGTON).**—Four cases of pulmonary tuberculosis treated. Three cases were definitely improved; in 2 of these cases tubercle bacilli disappeared from the sputum after treatment. The fourth patient had a profound reaction after the third dose of sanocrysin and died from toxæmia. Serum was used in this case, but it had no beneficial effect.

The conclusions of the Belfast Committee are as follows:

1. Sanocrysin is a distinct therapeutic advance in the treatment of tuberculosis in definitely selected classes of cases.
2. The undoubtedly good results that have been obtained must, however, be observed for a further term—say, at least one year—to see whether the results are permanent, or whether further courses are advisable.
3. Sanocrysin as a method of treatment is not suitable for general use, and with our present limited knowledge it should only be used in institutions equipped with the necessary apparatus, and under the direct control of sufficiently experienced physicians, with expert knowledge in the treatment of tuberculosis.
4. Further research is necessary in order to determine: (a) the class of case most likely to benefit by this form of treatment; (b) the correct size of dose for individual patients; (c) the intervals between the doses; (d) the length of the whole course of treatment; and (e) the significance of the clinical phenomena which would seem to indicate the discontinuance of the treatment.

#### GENERAL SUMMARY.

Experience in the selection and treatment of cases has greatly lessened the dangers attending the use of sanocrysin. The first collective report by the Medical Research Council described 2 deaths directly caused by sanocrysin out of a total of about 30 cases treated. This second report records only one similar fatality (Royal Victoria Hospital, Belfast) in a much larger number of cases treated—about 140. But the risk remains. There may be sudden or progressive exaggeration of the more serious symptoms of the tuberculous infection, or there may be a poisoning of the kidney, of the liver, and even of the skin with a drug dermatitis which is quite distinct from the relatively transient rash. All these dangerous features are far more liable to arise in the sanocrysin treatment of tuberculous patients than in the use of salvarsan for syphilitic or other infections. All patients under treatment must, therefore, be in bed and under close medical control.

In the last twelve months it has become the custom to give smaller doses of sanocrysin and at longer intervals than those used with the cases described in the first report. The patient is thereby spared from dangerous reactions and even from any great discomfort. It is, however, debatable whether this attenuation of the treatment for the sake of the patient's immediate welfare may not have the disadvantage of lessening the final benefit. The arguments on either side are given in two recent books by Secher<sup>1</sup> and Würtzen<sup>2</sup> respectively, when describing clinical results obtained in Copenhagen.

The special serum has rarely been used, and there is no fresh experience to record about it. Nor is there much more evidence upon the question whether a well marked reaction to sanocrysin can be accepted as a diagnostic test for tuberculous infection. It would, indeed, appear from the reactions seen by Fournier and Mollaret<sup>3</sup> in the treatment of human syphilis with a similar gold salt that such reactions are not specific for tuberculosis. As in the first report, it was again evident that there may be an advantage in collecting evidence from different clinical observers as to the possible benefit of sanocrysin treatment. Some thought that nothing more was seen than might have been expected as the result of prolonged rest under hospital or sanatorium control. But others were very emphatically of the opinion that sanocrysin did cause unusually quick amelioration of all the features of a tuberculous infection, especially in the lessening of sputum and disappearance of tubercle bacilli. The question of secondary infections of the lung tissue by other organisms has not been dealt with. The results described are considered only in their broad aspect of clinical recovery or deterioration, for there are no laboratory tests yet available for analysis of any possible changes in a patient's powers of resistance to tuberculous infection.

The Medical Research Council received, by the generous courtesy of Professor Moellgaard, a free supply of sanocrysin and serum for trial in Great Britain over a period of twelve months. The trial has shown how dangers may be averted, and, in the opinion of some workers, it has given indication that along the line of some such substance as sanocrysin there is definite hope of a drug treatment that will check the progress of a tuberculous infection and allow the patient's natural powers of resistance better play in finally arresting the disease. These various clinical reports, for which the Council is greatly indebted to the observers, will suffice to indicate to the medical profession the general need for extreme care in the use of sanocrysin, and also the particular types of infection in which it may be expected to cause some improvement.

SATURDAY, JULY 24TH, 1926.

## THE PRESIDENTIAL ADDRESS.

THE address of the President of the British Medical Association, delivered this week at the Annual Meeting at Nottingham, deals with many thought-compelling problems of medical work. Mr. Hogarth addresses himself primarily to medical practitioners. His aim is to discuss certain problems with his colleagues. But since these problems concern the public weal the address may be read with profit by a wider circle than the medical profession, as we have no doubt it will.

The part of the address that will make the largest appeal to the student of the times is the exposure of two apparently opposing tendencies to be found in current expressions of opinion outside medical circles. On the one hand there is a cry for greater freedom of medical practice. The public, it is said, is weary of medical etiquette and of the shackles of order and precedent. Some, who have the ear of the public in literary and dramatic affairs, deride the *Medical Register* and all it stands for, and protest against its continued limitation to those who, as diligent students, have sought to make themselves familiar with the human body, its form and functions; and with disease, its manifestations and mastery; and as they deride the hard-trodden road of achievement, so they exalt the unknown and mysterious, the clamant and blatant. Some of these, in the words of the President, are "good people, invincibly credulous and optimistic by nature, who chatter about cures and treatment as others chatter about politics, and on whose ears well syllabled words like 'osteopathy' and 'manipulation' fall with a sweetly modulated cadence of solace and hope. The other class consists of the ingenious rebels against all authority but their own, the sophists of the day." There is in the cry of these persons something of the blood-stirring appeal of the revolutionary which often strikes a spark in even the sanest minds. On the other hand, there is the direct reverse of this attitude to be found among a large section of the community. This is not a revolt, it is a reaction, a tendency to revert to a mediaeval attitude of mind which yearns after the super-authority or something whose efficacy is supernatural. It seeks to harness some ineffable influence to the chariot of progress, which seems to them to drag heavily and advance too slowly.

Both the revolutionary and the reactionary seek short cuts to ends which are equally the aim of scientific medicine. But the methods of attainment differ as the poles. Medicine aims at attainment by continuous experimentation and verification; it would make sure of the stability of each step of advance. Whereas the revolutionary and reactionary would take haphazard leaps into the unknown, with results the experience of generations has shown likely to be disastrous to those who are ministered to if not to the ministers of these cults. The President wisely shows that, steadfast as modern scientific medicine is in its adhesion to the road of experiment, observation, and verification, this steadfastness does not exclude, but most emphatically includes, a constant vigilance and preparedness "for the crash of old-established notions and for restless movements of insurgence along boundaries which once appeared to have been fixed

for all time." And, also, the ever-present recognition that "there is a certain healing power, a true *vis medicatrix*, in religion as in nature, . . . some serenity of mind in the patient, . . . some tranquillizing influence of the soul upon the physical stress and tumult of the senses—beneficent, soothing, healing activities in which [the doctor] and his art have had little or no share."

On more general questions the President's strictures on unbalanced rejoicings at improvements in bills of mortality are most pertinent. What good is there, he asks, in the mere prolongation of life either to the individual or the nation "unless there is a real capacity to enjoy it"? Our aim must be to raise the general standard of health among all ages of the community. But we still have among us "an enormous mass of bruised and damaged humanity which never enjoys robust health, which is continually ailing, . . . and never approaches full industrial efficiency." He observes that it has been the gradual recognition of these facts that has brought about a community medicine—an effort on the part of the State to concern itself more and more with the health of the nation. The establishment of the Ministry of Health bore witness, not to the sudden discovery of a new truth, but to the proved results of much admirable work which had been done in the previous half-century and to the need of its more resolute prosecution. Pure water, good drainage, better housing, industrial hygiene, compulsory notification of disease, licensing laws, all proved their effectiveness.

The scope of preventive legislation is almost limitless, and Mr. Hogarth sees the possibility of the State intervening more and more in the interests of public health. But with advantages he sees possible risks. A logical development in a socialist State might make all medicine directly subservient to the State. He concedes that such a system of State medicine might be worked, but adds: "Whether it would be as efficient as our present system, whether it would be as acceptable to the general body of the people, and whether the vastly increased cost would be repaid by equivalent advancement of medical knowledge or improvement in the public health, there is room for the very gravest doubts." Nowhere, he believes, is such a conclusion more likely to be realized than in the hospitals. He does not suggest that the hospitals would wither if the voluntary principle were abandoned. They would still multiply and prosper. Their orderly routine might possibly show an even more brilliant and imposing efficiency. But "there is something inherent in officialdom which freezes the genial current of the soul, and thaw it as you will by the application of whatever new principles of kindness and mercy it can never be thawed right out." That there must be changes in our hospital system he clearly recognizes. There must be close co-operation between hospitals; the elimination of that besetting sin of charitable effort, overlapping and wasteful management; and searching criticism of accounts by business men. Again, he points out that the modern voluntary hospital is no longer "the lazar-house of the destitute, the place to which homeless and plague-stricken outcasts crawled to die, or into which they were herded if they seemed too noisome and dangerous to be tolerated at large." The idea of the modern voluntary hospital is far larger and finer. The primary aim of care for the poor is in no way shelved or neglected. But the hospitals, from being mere infirmaries, have become the centres of the best medical and surgical skill in the areas they serve. So it is certain that we shall see the hospital idea still further expanded in the near

future, through a steady extension of the principle of the paying ward, and even of the paying hospital, for the use of the patient who pays according to his means. The interests of the middle classes deserve attention no less than those of any other class, and he does not think that the charitable donor is likely to object to middle-class patients receiving a share of the fruits of his charity. "He had a much more valid grievance against those who abused the freedom of the hospital and never contributed a penny to its funds." In his view of hospital development the President, we think, gives correct expression to the growing volume of opinion among all classes of the community, a fact that is illustrated by the recent paper by Mr. Sanctuary, the administrator of the Radcliffe Infirmary at Oxford, read before the Oxford Division of the British Medical Association, and reported elsewhere in this issue (p. 170). Mr. Sanctuary took an even bolder line: he urged that the voluntary hospitals should be available for all—the poor, the middle classes, and the rich alike, each paying according to their several abilities, and the doctor receiving the remuneration due for his services.

There is much matter for thought in this Presidential Address. It is eloquent because it is thought-compelling, and we believe also because it is of the quality of fruitful thought in that it stirs to action.

## ANNUAL MEETING NOTES.

### THE ANNUAL REPRESENTATIVE MEETING.

*Friday, July 16th.*

FULL reports of the first 'two days' proceedings of the Representative Body will be found in this week's SUPPLEMENT. The short notes that follow are meant to serve merely as an informal guide to some of the discussions and decisions.

The Representative Body met on Friday, July 16th, with what promised to be a "record" attendance, and with an agenda which, on the face of it, was probably the least controversial presented to the series of meetings held since the war. Accordingly, the debates throughout the day were somewhat discursive, and less progress than might have been hoped for was made by the evening. This is not to say that the matters discussed lacked interest, but merely that they provoked little controversy. The outstanding feature of the day was, of course, the report by the Chairman of the Organization Committee on the organization of the profession in South Africa, and the adoption by acclamation of the resolutions which set the final seal of approval on the settlement negotiated by Dr. Cox during his South African tour. Throughout Dr. Morton Mackenzie's analysis of the position as it had developed last year and his summing up of the steps by which obstacles once apparently insuperable have been surmounted, and throughout the speeches of the South African representatives and Dr. Cox's reply to the warm congratulations addressed to him, there was manifest a strong sense of the reality of the difficulties to be met, the danger of failure, and the solidity of the success achieved. But there was also a full appreciation of the fact that it was the spirit of true statesmanship displayed by the South African leaders that has rendered possible professional unity in South Africa under the auspices of the newly formed body to be known as "The Medical Association of South Africa (British Medical Association)." In the cause of that unity, and in the public interest, they, in the words of Dr. Morton Mackenzie, have given freely and as freely recognized the concessions made by the Association at home. It was a happy augury for the future that the report was made under the flag presented by the Wit-

watersrand Branch for display in the Great Hall of the House of the Association. Apart from the presentation of the South African report the session was hardly eventful. The amendments to standing orders governing procedure at the present meeting were adopted as a matter of course, and it may be hoped that some way of regulating the reservation of seats in a manner which will appeal to the collective sense of the representatives will be found by the Agenda Committee before next year. On the Chairman of Council's presentation of the several reports and memorandums before the meeting, the main items of interest emerging were the list of gifts presented to the Association during the past year, and the honorary membership conferred by the meeting on Dr. Hall-Edwards. Under the heading of finance there was enough discussion to indicate a healthy interest in the subject, but no substantial criticism was advanced. The discussion did, however, serve to clear the minds of representatives as to the extent of the Association's financial contributions towards the advancement of science, and the means by which it seeks to serve this end. The chief interest centred in the cordial expression of appreciation of the outstanding services rendered by the Building Subcommittee, both in regard to the Association's new headquarters and the disposal of its former house. It was only with a portion of the Science Committee's report that a point of sharp difference of opinion, or perhaps rather of sentiment, was reached. Here there was real danger that the efficacy of the scale for non-professional teachers and laboratory and research workers might be destroyed by motions designed to meet the hard cases of struggling institutions. The afternoon session opened with a sharp skirmish between those who, in the words of a critic, were either not trying to be heard or not trying to hear. As the outcome of a debate on the constitution of the standing Charities Committee the principle of territorial representation received general approval. A suggestion from Dr. Fothergill that in order to save time he should deal with two motions from Brighton together was very well received—possibly as a hint for others to follow. The discussion of those motions showed how often it may happen that the same idea arises both centrally and locally, and illustrated once again the activity of Brighton in exploring new fields of utility for the Association—in the one case co-operation with other professional societies in this country, in the other with foreign medical societies. The session closed with an unexpected outburst of feeling elicited by the old question of the length of time for which a member may retain books borrowed from the library. The solution accepted on the suggestion of the Chairman of Council appeared to the meeting generally to be both reasonable and practicable.

*Saturday, July 17th.*

The Representative Body met on Saturday with the prospect of a short session, though the agenda included at least three matters in which lay as well as professional opinion had been considerably exercised of recent years—namely, hospital policy, psycho-analysis, and the constitution and functions of the General Medical Council. Under all three heads definition of the points at issue and elucidation of the facts of the case, as opposed to surmises regarding the position, formed probably the most important work accomplished. The resolution on the treatment of accidents in hospitals was accepted as an uncontroversial application of the existing policy of the Association; but that relating to hospital case sheets, involving on the one hand ethical considerations, and on the other the danger of impairing practical efficiency by the rigidity of definition, was more debatable. Here the recommendation of Council was accepted as a necessary safeguard of a position open to attack, and as the nearest approximation to maintaining the relationship of doctor and patient as it exists

in private practice. The question of payment of the visiting consultant staffs of Poor Law hospitals raised the old issue between the dangers and the advantages of laying down any definite standard of remuneration. The acceptance of definite minima for services rendered on an attendance basis, and the remission to the Council of the question of rates for annual contracts, was probably the utmost advance that could be made in the circumstances. The discussion of psycho-analysis showed a marked division of opinion, not so much on a matter of principle as of practical politics. All were probably in sympathy with Dr. Woodroffe's statement about the difficulties of the general practitioner in this connexion, and with the desire to narrow as soon and as effectively as possible the existing field for misunderstanding. But those who followed Dr. Langdon-Down and Dr. Hawthorne in their opposition to the motion felt, as Dr. Buist briefly suggested, that a scientific association should work scientifically; knowledge was wanted before opinion, and the requisite knowledge on this subject did not exist. This was the assumption underlying Dr. R. G. Gordon's clear and informative speech. There seemed to be some division of opinion also as to the scope of the functions of the British Medical Association in connexion with inquiries of this nature, and as to the procedure proper to them. While the opponents of the Sussex motion argued effectively, Dr. Parry was successful in his determination not to be tied down to the original proposition brought forward at Bath, which the Sussex representatives had explicitly abandoned in favour of the present proposal. The discussion on the General Medical Council served two good ends. It allowed expression to a considerable and well founded feeling of dissatisfaction with the attitude taken up by certain sections of the public and the press, and permitted a vindication of the manner in which that Council had faced the resulting position by reference to the facts. It was an interesting commentary upon the theory of public transaction of business, as opposed to secret deliberation, that whereas the members of the lay press were very naturally requested to withdraw in order to ensure freedom of statement on the part of the members of the General Medical Council who explained its methods and machinery, when these statements had been made it was found that their publication would be definitely in the public interest. The ending of the debate by Dr. Dain's motion to proceed to the next business was an excellent example of the statesmanlike use of that method of procedure as opposed to its more frequent abuse in other assemblies. The installation of a microphone and "loud speakers" during the luncheon interval was the outcome of a protest from the back of the hall to the effect that a motion, thrice read to the meeting, had nevertheless not been heard by many members when the vote was taken. The immediate result was to allow the main body of representatives to hear those addressing them, but the speakers became forthwith wholly inaudible to the press and the platform and the front rows of the audience. When this had been adjusted Dr. Buist stood up to raise a diverting point of order—namely, to inform the Chairman that every "aside" upon the platform had become clearly audible at the back of the hall! Apart from such minor embarrassments, it appeared that the introduction of this device enabled the Representative Body to follow with closer attention the conduct of its business.

#### LUNCHEON TO OVERSEA REPRESENTATIVES.

On the first day of the Annual Representative Meeting the officers of the Association and the Chairmen of the Organization and Dominions Committees gave a luncheon party at the Victoria Hotel to welcome the representatives of oversea Branches and Divisions who are taking part in

the proceedings at Nottingham. Dr. H. B. Brackenbury, Chairman of the Representative Body, who presided, said how glad he and his colleagues were to have this opportunity of making the personal acquaintance of oversea members. Their affairs were constantly before the Association at home, and formed a most interesting part of its work. The presence of representatives from distant lands helped towards that consolidation of the profession in every part of the Empire which the Association had at heart. Dr. K. B. Alexander (South Africa), in a few words of acknowledgement, spoke of the great value of personal meetings and discussions, and quoted the success of Dr. Cox's visit to South Africa as a case in point. Lieut.-Colonel F. F. Elwes (South India and Madras) said attendance at the Annual Meeting brought home to these from abroad the fact that they belonged to one body which was looking after its members' interests everywhere. Dr. R. J. Bull (Victoria) brought a message of loyalty and goodwill from Australia, and added that his own reception at headquarters and in Nottingham made him feel among friends. The brief and informal proceedings—an agreeable interlude between two busy sessions—ended with the toast of "Our Hosts," proposed by Dr. P. J. Chissell (Ceylon). The joint hosts, with Dr. Brackenbury, were Sir Robert Bolam (Chairman of Council), Mr. Bishop Harman (Treasurer), Dr. Morton Mackenzie (Chairman of the Organization Committee), and Sir Jenner Verrall (Chairman of the Dominions Committee). The other oversea guests present were Dr. H. W. Dyke (Orange Free State), Dr. G. S. Woodman (Mesopotamia), Professor J. W. C. Gunn and Dr. E. A. Seale (Cape of Good Hope), Dr. C. B. McHutchinson (Malaya), Dr. E. F. Hatton (Grenada), and Dr. Gregory Sprott (Tasmania). The company also included the President-Elect, Mr. R. G. Hogarth, and the Honorary Local General Secretary, Mr. A. M. Webber; Dr. J. A. Macdonald, Dr. J. Barcroft Anderson, and Dr. F. J. Gomez; together with the senior officials of the Association, and the Solicitor, Mr. Hempson.

#### THE CHURCH SERVICE.

A special service for the British Medical Association was held at St. Mary's Parish Church, Nottingham, on Tuesday afternoon, when the President, the Chairmen of Council and of Representative Meetings, the Treasurer, and other officers and a very large body of members attended, wearing their academic gowns. There was also a civic procession, headed by the Mayor and the Sheriff of Nottingham. The service was conducted by the Rev. Thomas Field, D.D., vicar of Nottingham, and the sermon was preached by the Bishop of Manchester (the Right Rev. W. Temple, D.D.). The sermon was on the theme that the lower forms of existence had their meaning just in the degree in which they became vehicles for the higher forms. The preacher said that the Divine method of creation had always been, in his conception, to introduce the higher in order to develop to its full capacities the lower, and to reveal within it new elements. The trend of modern knowledge, in his view, made easier and not more difficult the intellectual acceptance of the essence of the old traditions. It was supremely difficult, he said, for anyone of his own generation (the bishop is still in his forties) to understand what all the trouble over evolution in the last century had been about, or was about now. No doubt that was partly because he was brought up in a home where the new thoughts were already familiar, and so his own early training was adapted to them; but he had great difficulty in thinking himself into the position of those to whom such ideas as evolution came as a shock. None the less, it did seem quite plain to him that the essential features of Christian doctrine fitted in with the newer scheme of thought far more coherently than they did with

the more static view which was prevalent in the days of our grandfathers. Speaking of the origin of evil, the bishop said that this question, however curious, was singularly unimportant. It had very little practical bearing on the really important question—not how evil came, but why it was here and what we were going to do now it was here. It was clear that in the Christian view, and, he thought, in what might be broadly termed the historico-scientific view, the struggle with evil was the main element in the significance of life and of reality; and that again was at the heart of Christian conviction. In the closing passages of his sermon the preacher spoke of the very close and intimate relation between those who were primarily concerned with healing evil in its bodily form, which was called disease, and evil in its spiritual form, which was called sin. Both Churchmen and medical men were engaged in the same task and struggle. The closer they could work together the better it would be. The stronger the spiritual life among those concerned with physical healing, the better would it be alike for themselves and for those who profited from their ministrations. He had been specially asked to call attention to the Guild of St. Luke, which existed to band together the members of the medical profession according to the rites of the Church of England. "But whether by that means or other means, just as we need your support on the Church's side if we are not to fail miserably in all that we set our hands to do, so you need, not only for the health of your individual souls, but for the full efficacy of your professional work, the heightening of your own spiritual powers to the utmost by the opening of your hearts to receive the love of God, and by the making of your spirits the vehicle of His Holy Spirit." The offertory was on behalf of British Medical Association charities.

#### "THE BOOK OF NOTTINGHAM."

A beautiful volume, *The Book of Nottingham*, resembling in size and style that issued by Bath last year, has been produced by the Printing and Publishing Committee at Nottingham, and a copy has been given to every member attending the present Annual Meeting. This volume, like its predecessors, is not intended to serve as a guide-book. Its purpose is to make the reader acquainted with the history and natural features of Nottingham and Nottinghamshire from the earliest times to the present day, and to tell him something of the staple industries of the town. A large part of the text is from the pen of Mr. E. L. Guilford, M.A., to whom our readers are indebted for most of the descriptive and historical notes on Nottingham and its neighbourhood which have appeared in recent months in the *BRITISH MEDICAL JOURNAL*. Mr. Guilford's intimate knowledge of local history and his literary skill have been placed freely at the disposal of the committee. His articles are supplemented by a synopsis of the varied scenery and geology of the country around Nottingham, by Dr. W. Alfred Richardson, lecturer in petrology, and Mr. Sydney G. Clift, lecturer in geology, at University College, Nottingham. The book opens with an outline of the history of the town, and in a series of notes on modern Nottingham particular attention is paid to the hospitals and to University College. It is a pity, as the preface remarks, that its growth from a small agricultural community of the Middle Ages to a large commercial and industrial centre has only been accomplished by the covering up of ancient landmarks and ruthless sacrifice of the picturesque for the utilitarian. "Gone are the narrow streets with overhanging gabled houses; and the old gates that marked the confines of this ancient city." Nevertheless, the busy Nottingham of to-day has a good deal to attract the antiquary; and the surrounding country abounds with famous houses, monastic remains, and interesting towns and villages, many of which are here

described and illustrated. In a chapter headed "Famous Men of Nottinghamshire," the exploits of Robin Hood and of the Fools of Gotham are treated in a spirit of becoming levity, and a sketch is given of John of Arderne, the father of English surgery, who practised at Newark from 1349 to 1370, and whose career has been made familiar through the writings of Sir D'Arcy Power. Another medical name honoured in the neighbourhood is that of the physiologist, Marshall Hall, M.D., F.R.S., who was born at Basford in 1790, and practised as a physician in Nottingham from 1817 to 1826. The volume is excellently printed in clear large type on good paper, and the many illustrations, reproduced from drawings, photographs, plans, and old prints, add greatly to its interest and value. The frontispiece is from a portrait of the President, Mr. R. G. Hogarth, and there is a beautiful reproduction in colours of the characteristic landscape by Arnesby Brown, R.A., "May Morning, Nottingham," exhibited four years ago at the Royal Academy: the original, in the possession of the corporation, hangs in the Nottingham Museum and Art Gallery. The chapter describing the leading trades and industries of Nottingham includes, of course, sections on hosiery and lace making, and on the manufactories of the firms of Boots and Player; there is also a note, particularly interesting to us, on the development of modern methods of printing. Everyone knows that the town is famous for its lace, its tobacco, and its chemicals, but in recent times it has become an important centre also of the printing trade, and this volume is a good example of what can be done by a Nottingham firm of printers. Indeed, the chairman and the secretary of the Printing and Publishing Committee—Dr. Eric Snell and Dr. N. P. R. Galloway—write altogether too modestly in their preface about the results of their labours. *The Book of Nottingham* will be valued as a delightful souvenir by everyone who has taken part in the ninety-fourth Annual Meeting of the British Medical Association.

#### THE STUDY OF CANCER.

THE Departmental Committee of the Ministry of Health appointed in 1923 to consider available information with regard to the causation, prevalence, and treatment of cancer has issued two more reports.<sup>1</sup> No. 33 is by Dr. Major Greenwood, and deals with the natural duration of cancer. The data analysed, with all Dr. Major Greenwood's customary care and insight, were obtained from several hospitals, and included 4,238 cases relating to seven primary sites; they are utilized in various ways, but principally to ascertain the natural duration, in order to be able to measure the effects of treatment. Any numerical measure of cure must, Dr. Greenwood points out, take account of three quantities: (1) the average duration of life of a person, of the same age as the patient, but not known to be suffering from the disease; (2) the average duration of life of a person suffering from the disease and left untreated; (3) the average duration of life of a person suffering from the disease and treated in the manner the value of which it is desired to test. The case of cancer of the breast is taken as an example, and the assumptions which must be made are set out. It is shown that the normal expectation of life of a woman aged 55 is 18.87 years. The expectation of life of a woman with untreated cancer of the breast is 3.25 years; that of a woman operated upon under "average" conditions is 5.74 years, and of a woman operated on under the best conditions 12.93 years. By "average" conditions are to be understood conditions

<sup>1</sup> Ministry of Health. Reports on Public Health and Medical Subjects. No. 33: *The Natural Duration of Cancer*, by Dr. Major Greenwood; price 8d. No. 34: *The Late Results of Operation for Cancer of the Breast (Leeds)*; price 6d. H.M. Stationery Office, London, Manchester, Cardiff, and Edinburgh.

in which women usually present themselves for treatment—that is to say, in conditions not too far advanced to render operation with a view to eradication hopeless. By “best” conditions is to be understood those of a patient whose cancer is strictly localized, does not involve the skin, and has not affected either axillary or supraclavicular glands. No. 34 is a report on the late results of operation for cancer of the breast, and shows the after-histories of women operated upon for primary cancer of the breast in Leeds General Infirmary and the Hospital for Women and Children during the years 1910-13 and 1919-21. One of the general conclusions is that if the complete operation is undertaken while the growth is still confined to the breast it is rare for the patient to die of the disease within ten years. If the growth has ceased to be local it is rare for a patient to be alive ten years after operation. While the growth was still local 90.1 patients were alive ten years after operation. When the axillary glands were involved 91.3 were dead within ten years of operation, and of more advanced cases 94.4 were dead within ten years of operation. This is well summarized in the epigrammatic statement that the “survival rate is inverted as soon as the cancer has passed beyond the breast.”

#### FORECASTING EPIDEMIC SMALL-POX.

THE Medical Research Council has just issued<sup>1</sup> an interesting study of Indian medical statistics by Sir Leonard Rogers. In a preliminary investigation he had ascertained that in the North-Western area major epidemics of small-pox followed failure of the south-west monsoon rains; but when the whole peninsula was considered it appeared that the actual amount of rain was not the determining factor. Thus, while in the seven provinces which receive their main supply of rain during the south-west monsoon from June to October there is, during this period, a great fall in the incidence of small-pox, yet the north-east monsoon—which is the chief source of supply in the south-eastern parts of Madras—is not associated with a decline of mortality from small-pox in that area. Detailed investigations make it probable that a more reliable indication of coming epidemics is given by the absolute humidity of the atmosphere. With this clue the explanation of the anomaly in Madras is reached. There “the north-east monsoon rains of October to December are seen to occur at a time of falling monthly mean temperature; they are consequently accompanied by a falling absolute humidity, especially during the rains of November and December, which we have seen are followed by a rapid rise in the incidence of the disease.” This thesis is supported by an examination of all the available data, illustrated by numerous charts and tables. Cases naturally occur when the correspondence is not good, but these may be explained. For instance, in the Central Provinces there was an exceptional prevalence of small-pox in 1895, although the rains were good and the humidity high. But this followed a period of five years in which the small-pox rate was low and vaccination neglected, so that an accumulation of susceptible persons might be the explanation. The method of correlation shows in each case a negative correlation between the absolute humidity of one year and the small-pox rate of the following year. In only two of the provinces, however, are the values, taken alone, significant from the statistical point of view; but, as Sir Leonard Rogers notes, the epidemic often begins in the year before that containing its maximum, so that the data are not very suitable for summary presentation by means of single constants. The question is raised whether this means of forecasting could be used outside of India, and it is sug-

gested that in other countries with definite rainy seasons and high temperatures the criterion might be useful. He indicates, among other districts, Eastern Queensland, Central and much of South America, and the Southern United States as suitable for study. For the reasons given this method is not, perhaps, likely to be of much service to epidemiologists in this small island, but its value in many continental areas may be great. If there was a reasonably trustworthy means of prediction a good deal might be done—for instance, by an intensive vaccination campaign—to reduce the mortality of the epidemic. Hence Sir Leonard Rogers has performed a valuable service in bringing this method to the notice of epidemiologists, and the value of his report is enhanced by the publication of the actual data. Most readers will no doubt be content to read the text and examine the diagrams, but the few who may wish to try refinements or modifications of the author's process will have the means of doing so.

#### IMPERIAL CO-ORDINATION OF MEDICAL RESEARCH.

AMONG the addresses to the Congress of the Universities of the Empire held at Cambridge last week, that by the director of the London School of Hygiene and Tropical Medicine had a special appeal to the medical profession at home and abroad. Dr. Balfour said that at present much time was wasted, energy dissipated, and money thrown away owing to the fact that in the great and important domain of tropical medicine men were to a large extent working in watertight compartments. While it was true that such publications as the *Tropical Diseases Bulletin* served to keep workers conversant with the researches carried out by others, this only partially met the difficulties. Some organization was required to lay down lines of research work (which need not appear to be immediately profitable), follow up what had been done, and decide not only what results were worth recording, but how best they could be recorded. At the moment India alone had done anything in this direction. There a Scientific Advisory Board met several times each year to consider the medical and sanitary research work which was being done and to discuss future lines of progress. The Indian Research Fund, which controlled the monetary resources, did not allot funds without obtaining the opinion of the board. There was no link, however, between the board and any institution in this country, and the want was badly felt. Dr. Balfour suggested that the Indian board should be in touch with some body such as the Medical Research Council. That Council, which had accomplished so much in this country, had not yet, to any great degree, extended its activities to questions of tropical import—from its constitution it was not at present in a position to deal with them unless they were common to both tropical and temperate climes. It was curious that while the Indian board worked in co-operation with the League of Nations it was not officially in touch with the scientific activities in the mother country. Dr. Balfour thought it essential that there should be in London some central organization which would consider and put forward suggestions for exploration, which would keep in touch with and encourage the workers themselves, which would collate and disseminate information, and which would arrange for the selection and training of personnel. He saw no insurmountable difficulties in such a scheme, especially if the Medical Research Council became the nucleus. A comparatively small expansion of its staff and resources would enable it to serve as such a nucleus and to keep in close touch with the Colonial and India Offices and with the Foreign Office (under whose control the Anglo-Egyptian Sudan came). The recent appointment of Dr. A. T. Stanton as chief medical adviser to the Secretary of State for the Colonies was a first step in the right direction, and if there were

<sup>1</sup> *Small-pox and Climate in India: Forecasting of Epidemics.* By Sir Leonard Rogers, C.I.E., M.D., F.R.C.P., F.R.S. (Medical Research Council, Special Report Series No. 105; pp. 22 + tables and diagrams.) 1926. H.M. Stationery Office. Price 2s. net.

attached to him a number of liaison officers it would become possible to look forward to a group of medical officers at the Colonial Office which, in close touch with the Imperial Research Council (or whatever it might be called), would be of the greatest value in supplying expert and up-to-date information. Another hopeful development, Dr. Balfour said, was the recent establishment of the Committee of Civil Research—a committee which might be, at least in part, incorporated with the council which he suggested. In each of the African colonies there should be a department of research, just as there was a department of public works, which would be concerned with all the branches of science—medical, veterinary, agriculture, forestry, botanical, geological, and so forth. The necessary funds might be obtained by grouping several colonies together—a scheme specially feasible in West Africa, the two Rhodesias, and the Sudan and Uganda. The Department of Research, in order to steer free of departmental jealousies, might well be placed under such a neutral department as that of education, if it were quite impossible for it to stand on its own legs. This plan had already been attempted with complete success by Sir James Currie in the Sudan. Education itself would benefit immensely by being linked up with all the research activities of those lands where it was endeavouring to make the native a wiser, better, and healthier citizen. The new London School of Hygiene and Tropical Medicine could, Dr. Balfour concluded, play an important part in co-ordinating and assisting medical and hygienic research throughout the empire, and might be one of the weapons by which the Central Research Council in London would wage an empire-wide war on ignorance and disease.

#### CHINESE HOSPITAL, SHANGHAI.

THE Chinese Hospital, Shantung Road, Shanghai, was founded eighty years ago by Dr. William Lockhart. It is staffed by members of the London Missionary Society, and controlled by British trustees. Recently the hospital has received, under the will of the late Mr. Henry Lester, an old resident in Shanghai, the magnificent gift of £350,000 in money and land. With these funds it is proposed to reconstruct the hospital on modern lines, to establish outside the city of Shanghai a home for convalescing and other patients, and to form an endowment fund for the institution. The report of the hospital for the year 1925, by Dr. Cecil J. Davenport and some of his subordinates, gives an interesting account of the work of the institution during the difficult period of the strike. In consequence of the boycott patients left the wards and attendances in the out-patient clinics fell off markedly. At times the whole Chinese staff threatened to resign, but better counsels in most cases prevailed. One resident Chinese doctor departed, leaving a picture of skulls and daggers on his bedroom wall; and four senior assistants and nurses left to join in the fray. The rest of the staff remained faithful to their posts. They were kept busy attending to persons who were wounded in the riots. In the report by Dr. Agnes Towers on the women's hospital a big drop in the in-patient admissions for 1925 is attributed partly to what must seem a curious cause to readers in this country. The "women opium suicides" were sent to a different part of the hospital. It is satisfactory to learn, however, that the suicide wave seems on the wane, fewer cases of suicide from swallowing match-heads having been seen than in former years. This form of suicide, says Dr. Towers, is very fatal, as the patients do not reach the hospital until the poison has had time to get thoroughly absorbed. In the men's wards nursing is done by young male nurses, assisted by coolies for sweeping and cleaning. The male nurse is apparently not easy to discipline, but on the whole is fairly satisfactory considering that he is a

man. The funds of the hospital show a slight balance on the right side, and with the generous gift of Mr. Lester its future should be assured.

#### A GREAT SURGEON'S COUNTRY SIDE.

IN addition to being a scientific surgeon in the first flight Sir Rickman Godlee was a many-sided man, though from innate modesty and reserve many of his accomplishments were hidden from all but his close friends. He was a linguist, a biographer, an artist, a poet, a botanist, an ornithologist, and more; as Sir George Newman points out in a sympathetic memorial sketch, all too short, which is attached to *A Village on the Thames: Whitechurch, Yesterday and To-day*,<sup>1</sup> a collection of charming essays written, without any thought of further publication, for the parish magazine, and now given to a wider audience by Lady Godlee, who supplies their history in a pleasing foreword. These fifty-two articles, the last three of which were ready for the press at the time of his sudden death on April 20th, 1925, are redolent of the country and the peaceful waters of the Thames, and reflect the wide interests of the few years of retirement after a busy professional life. They show an ideal realization of that desire to retire which so many men have but so comparatively few achieve. The first eight tell the story of the surroundings of Whitechurch in accounts of "The ancient Thames," "Locks and weirs," and "Ancient earthworks," while among the others there are many of a wider scope of birds, beasts, and insects, place names and surnames, coaches and railways, the last bringing into prominent the seclusion of his home, where "we Whitechurch folk hear indeed an occasional whistle and the distant roar of the trains when the wind is south-west, but even from the top of the hill it is hard to catch a glimpse of them until they are out of sight!" Charming written and well illustrated, especially with a photogravure of this smiling high-minded man sitting with his dog on a wheelbarrow in his garden, these essays are just the companions to take on a holiday.

#### THE ROSS INSTITUTE AND HOSPITAL FOR TROPICAL DISEASES.

ON July 15th the Prince of Wales opened the Ross Institute and Hospital for Tropical Diseases at Putney Heath of the origin and nature of which we gave an account last week (p. 129). The Prince of Wales was received by the Duchess of Portland, president of the institute, and by Sir Charles McLeod, the chairman, who presented an address and the key of the building. The Prince of Wales in reply, said that malaria, which had been one of the most deadly and elusive of tropical diseases, was now certain to be defeated, thanks to the achievements of Sir Ronald Ross. In the Sir Alfred Jones Laboratory in Sierra Leone the Prince had seen, only a few months ago, the remarkable progress which had been made in the campaign. No single discovery in recent times had earned the gratitude of so many human beings as the discovery made in India in 1897 by Sir Ronald Ross, who, as had been well said, "made one-third of the world inhabitable." With the sincere hope that further public support for endowment would be forthcoming, the Prince of Wales declared the institute and hospital open. After a dedicatory prayer by the Bishop of Southwark, a vote of thanks to the Prince was proposed by the Duchess of Portland and seconded by Sir Ronald Ross. The guests attending the ceremony were permitted subsequently to view the grounds of the hospital.

## THE CONGRESS OF CHEMISTS IN LONDON.

THE annual meeting of the Society of Chemical Industry in London this week was enlarged into a congress of chemists. On Monday, July 19th, at a meeting of the Institution of Chemical Engineers, the EARL OF BALROUN was presented with the Messel medal, and delivered the Messel memorial lecture, and an exhibition of British chemical plant at the Central Hall, Westminster, was opened by Sir Max Muspratt, president of the Federation of British Industries. On Tuesday morning, July 20th, the annual meeting of the Society of Chemical Industry was held, and the retiring president, Mr. W. J. U. Woolcock, delivered an address on the present position of the society. He pointed out that through co-operation it had become possible, for the first time in the society's history, to make the annual meeting a nucleus of a congress of chemists, representative of sixteen scientific and technical associations. He hoped also that in time the electrical engineers would be associated with their society. Co-operation had led to the formation of a bureau of British chemical abstracts, and by this means duplication in publication was avoided. The Chemical Society published abstracts in pure chemistry, and the Society of Chemical Industry those in applied chemistry. He called attention also to the formation of a fuel section of the society, for matters relating to fuel research and practice.

*Scientific and Industrial Problems of Hormones.*

On the same day the London section of the Society of Chemical Industry held a joint meeting with the Biochemical Society. The chair was taken by the Rt. Hon. Sir ALFRED MOND, and the subject for discussion was the scientific and industrial problems presented by the hormones—the natural drugs of the body. The first paper was read by Dr. H. H. DALE, F.R.S., on the experimental study and the use of hormones. Dr. Dale described the history of adrenaline from the time of Dr. George Oliver's experiments, and its isolation by Professor Abel in America, to the researches into its structure by Dr. Jowett. The Cambridge school of physiologists found that adrenaline might be said to produce all the vascular and visceral reactions which accompanied, and, according to one school of psychology, provided the basis for, the emotions of anger, excitement, and fright. There was evidence that the suprarenal glands supplemented the normal sympathetic control of the viscera when the organism prepared for combat or flight; while traces of this hormone in the blood probably helped to maintain a healthy tone and readiness of reaction in the small peripheral blood vessels. Apart from asthma, however, the chief condition for which adrenaline was used was the local production of bloodless mucous membranes for surgical purposes. From the chemical and manufacturing point of view, said Dr. Dale, adrenaline already furnished a complete story, if not a closed chapter. For the biochemist the fascinating problem of its origin in the body still remained. But of the active principles of the cortex of the suprarenal gland nothing was known; it still presented a problem to biochemical research, and ultimately to biochemical manufacture.

From the thyroid gland Kendall, in America, about ten years ago, isolated the active iodine-containing hormone thyroxine, which could now be prepared in practicable quantities, so that there was no doubt that sooner or later it would be produced by artificial synthesis. The active principles of the posterior lobe of the pituitary body, of insulin from the pancreas, and of secretin from the intestinal mucous membrane, were protein derivatives, or closely associated with such derivatives, and could not be separated from them without losing their specific activities. Consequently the manufacturer had to obtain his raw material from the abattoir in a state of absolute freshness. But the stability of the principles, once obtained, was considerable, if their reaction was weakly acid. Pituitary extract was invaluable in obstetrics. If the manufacturer obtained absolutely fresh material, simple extraction by boiling acidulated water gave an extract of high potency, and, at acid reaction, of great stability. But the gland

was extraordinarily sensitive to antilytic change or bacterial action, so that the variations in activity of samples of the extract had been something of a scandal to scientific manufacture, and a danger to life. If ever the principles were to be isolated for examination, it could only be by the close co-operation between industry and biochemical skill. The right method of extraction for insulin took many years to discover, but Professor Abel claimed that he had now isolated insulin as a pure crystalline substance. Evidence was now accumulating that the maintenance of a steady percentage of free glucose in the blood was due to a delicate balance between the action of insulin and the antagonistic effects of adrenaline, thyroxine, and pituitrin. Insulin was an example of what could be effected by co-operation between the scientifically organized factory and the academic laboratory; and the scientific industry of this country had reason to be proud of the fact that, within eighteen months from its introduction, production had increased so greatly that a balance was available for export, and the original price was reduced to less than one-eleventh of that originally required. The great need, however, was biological standardization. Even with adrenaline and thyroxine it was doubtful whether adequate chemical criteria of purity were yet available. It was possible even for the conscientious manufacturer to make, by apparently identical methods, preparations with a wide variety of activities, in the absence of physiological control. But the term "biological standardization" had too often been used, to its inevitable discredit, merely to represent the effort of a manufacturer to ensure that different issues of his own product had a rough uniformity of action. The activity of these potent preparations must be defined in, possibly empirical, but internationally valid units.

Dr. H. W. DUDLEY dealt with the difficulties of isolating in a pure condition the principles of pituitary gland and of insulin. The posterior lobe of the pituitary gland in oxen was so small that to yield a kilogram of the dried material 10,000 oxen were required, and probably less than 0.1 per cent. of the dried tissue represented active principles. With insulin also probably the major portion of the preparations was inert material. The chemical investigation of these hormones encountered difficulties equally formidable on account of their complexity and instability. No chemical tests for their presence being known, they must, after each attempted step in their purification, be recovered in a form suitable for a quantitative physiological test, while their stability was such that none but the mildest chemical manipulations caused their destruction. In the case of the pituitary hormones the preparation of crystalline salts had been reported, but in no instance had the observations been confirmed. It was now possible to concentrate the entire insulin activity of the pancreas into a very small bulk, which was the insulin of modern chemical technology; but whether the crystalline substance isolated by Professor Abel—and which he stated had a physiological activity slightly greater than that of the best commercial preparations—was the hormone in chemically pure form could not be determined until further evidence was provided.

Mr. FRANCIS H. CARR said that, with the help of the physiologist, the technical difficulties of manufacturing hormones, though somewhat exceptional, might be compared to those encountered in other departments of fine chemical manufacture. Beginning in the slaughterhouse, the raw material (the glands) was laid out in thin layers in cold, dried air, and was quickly frozen. But, even when frozen, adverse changes were not entirely inhibited, so that the frozen glands must be worked up as promptly as possible. Crude extracts containing insulin were stabilized at normal temperatures by bringing the solution to a pronounced acid condition, and removing enzymes by filtration. Continuous treatment of small amounts was better than treating larger quantities in intermittent batches. Grinding of glands should be carried out in two stages, between which acid and alcohol should be incorporated to make the mixture stable. In the stage of concentration low temperature was again of importance, the destruction of insulin being a function of the factor temperature multiplied by time. The ultimate purification of high-

grade insulin depended upon careful steering through a maze of operations, success in the final stage being largely due to Dr. Dudley's method of precipitating the insulin with picric acid, and subsequently regenerating it as hydrochloride. The preparation of thyroxine, originally discovered by Kendall, had recently been greatly improved by the introduction of Harington's method, whereby twenty-five times as much thyroxine was produced. The advantage of thyroxine was that, being a crystalline chemical substance, its purity could be determined by chemical means. Mr. Carr said that the manufacture of hormones which he had described had been achieved by the alliance of manufacturers with State laboratories and universities; and in both cases substantial reduction in cost had been achieved, bringing the prices well within the reach of the poor.

Dr. H. A. D. JOWETT sketched the history of adrenaline down to the present day, when the isolation and identification of the hormone had been completed and the synthetic process had been worked out on the commercial scale, so that a synthetic adrenaline—identical in all respects with the natural product—was available and was sold under the name of "suprarenin synthetic."

Dr. G. BARGER, F.R.S. (Edinburgh), described recent progress in the chemistry of thyroxine, referring in particular to the work of Kendall and Harington, of which an account in some detail was given in our issue of June, 26th (p. 1092).

The difficulties attending the biological assay of hormones were discussed by Dr. J. W. TREVAN. They depended, he said, almost entirely on the variability of the animal or organ used as the indicator of potency. Not only did different individuals of the same species give different responses to the same drug, but the responses varied from day to day in the same animal. A biological assay must, therefore, always take the form of a direct comparison with a standard preparation. The specification and preparation of international standards for insulin and pituitrin by the Health Committee of the League of Nations would render the provision of preparations of constant activity much easier, and it was to be hoped that tests for the other hormones would be devised of sufficient accuracy.

## ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual meeting of the Royal Medico-Psychological Association in London, the earlier proceedings of which were reported in our last issue, was continued from July 14th to 16th, under the presidency of Dr. J. R. LOND.

### *Encephalitis Lethargica.*

Some observations on encephalitis lethargica were contributed by Dr. MACKENZIE WALLIS, and in another paper Dr. C. FARRAN-RIDGE described some symptoms referable to the basal ganglia occurring in dementia praecox and epidemic encephalitis. Dr. Wallis said that the chief feature of encephalitis in laboratory animals appeared to be the profound effect on the kidneys, liver, and spleen; there was an almost complete absence of nervous symptoms. Evidence was shown of hepatic insufficiency and also of hyperglycaemia and glycosuria, but these changes did not appear to be confined to encephalitis; they occurred in other filter-passing diseases—vaccinia, for example. The experimental investigations furnished an approach to the clinical problem of encephalitis lethargica in man. Dr. Wallis described the tests which he had employed—namely, the laevulose tolerance test, the lipase content of the serum, and the cholesterol content of the blood—and said that forty cases of undoubted encephalitis lethargica had been investigated by means of the tests for hepatic insufficiency, and twenty-five of them showed evidence of hepatic derangement. Many of these cases came to the *post-mortem* room, where the tests were confirmed by histological examination. The acute cases had shown a raised lipase content and also a raised cholesterol content of the blood, and a positive indirect van den Bergh test. The most striking results occurred in cases of mid-brain tumours. The relation of the mid-brain to the carbohydrate metabolism and to the hepatic function had received further confirmation from these results.

### *Educational Provision in London for Subnormal Children.*

The members of the association paid a visit to the London County Hall, where they were received by the chairman and vice-chairman of the Mental Hospitals Committee (Mrs. Dunn Gardner and Mr. A. C. Moring) and the chief officer of the mental hospitals department (Mr. H. F. Keene).

Dr. F. C. SHRUBSALL read a paper bearing the title "Educational adaptation of the individual child," which was in reality a statement of the educational provision in London, especially for subnormal children. He said that the number of schools for the blind and deaf was 48, for the physically defective 37, for the mentally defective 78, and for tuberculous or pre-tuberculous children (open-air schools) 12. The number of school doctors was 89, of whom 25 were on whole-time engagements, and the children examined in 1925 numbered 316,722, or about half the total number of pupils in the elementary schools. Children were examined four times in their school career—first on entrance, then during the years in which they attained the age of 8 and of 12, and finally a few months before leaving school in their 15th year. The improvement of the physique of the children, Dr. Shruballs claimed, had been very marked, and there was evidence that the 8-year-old boy averaged half an inch taller, with a similar gain in weight, as compared with the boy of corresponding age twenty years ago. He gave some interesting particulars of the psychological investigations pursued. About one child in ten showed superior abilities, and the attempt was made to select such children by examination at 11 and transfer them from the elementary to the secondary schools. Altogether the child was now considered as an individual, and attempts were made to modify the educational machinery to suit the child rather than to follow the former procrustean method whereby the child was made to fit the machinery.

Afterwards the members were shown over the County Hall, visiting the magnificent council chamber, also the medical examination rooms and laboratories, and then they inspected the automatic telephone system, and the lighting, ventilating, and heating arrangements. Practically all the rooms have indirect lighting by means of bowl fittings. In the sub-basement the visitors saw the six boilers which supply hot water through thirty miles of pipes to more than two thousand radiators.

### *Psycho-Analysis and its Development.*

On Thursday morning (July 15th) a discussion on psycho-analysis and its development was opened by Dr. W. A. POTTS, who said that in the mind there was a mass of past experiences which could not be readily remembered, and some of a person's mental processes eluded his observation. The modern psychologist said that the forgotten memories and the hidden mental processes were in the unconscious or the subconscious mind, which was below the threshold of personal consciousness. Freud's method of exploring the unconscious mind was termed psycho-analysis, and was founded on the idea that dreams were neither accidental nor meaningless, but constituted the royal road to the unconscious mind. Freud found in this unconscious mind the real motives of unusual conduct; he held that the unconscious consisted largely of unfortunate experiences in early life, many of them of a sexual nature, and that the abnormal conduct was due to a conflict between the conscious and the unconscious minds, owing to primitive desires being stifled. In Freud's view, sex included such fine instincts as the love of the mother for her child. One of the chief objects of psycho-analysis was to discover repressions. It had been unjustly urged against psycho-analysts that to regard desires as natural meant that they should have indiscriminate gratification; nothing should be encouraged which would be against either the community or the individual. Jung did not agree with the emphasis which Freud placed on sex, and contended that present ideas often had more power than had past experiences. Dr. Potts avowed himself an adherent to Jung's school. The object of the analyser was to draw the patient to a conception of the manner of man he was, and that his troubles were really part of general human

experience. Dr. Potts insisted that it was desirable that those who practised psycho-analysis should themselves have been subjected to the process by another. If those who had not entered fully into it worked on this method it was liable to bring discredit on it. It was not a form of treatment for acute mental disease; both psycho-analysis and psychological analysis were special kinds of education, which prevented the recurrence or development of mental disorder which otherwise seemed inevitable. This process by no means disregarded physical ailments in mental disease.

Dr. WILLIAM BROWN (Oxford) agreed with Dr. Potts in a general way, but insisted that, whether the method of Freud or that of Jung were followed, it was the same in quality. He believed that Jung's insistence on the influence of present factors would not be denied by Freud. He gave a sketch of Freud's most recent work, on the general libido theory, which was an attempt to explain difficulties of evolution in the moral life in terms of libido distribution. In psycho-analysis dissociations of one kind and another were overcome, while the unsatisfactory nature of his philosophy was revealed to the patient, thus helping him to find another philosophy of life. He agreed that all who intended to specialize in this branch should themselves have been analysed.

Dr. A. WOHLGEMUTH approached the matter from that of pure science, having no regard to the therapeutic value of the method or otherwise. He objected to the term "the unconscious mind," as it was no more than a process. It was not correct to credit Freud with the discovery of the unconscious mind. He contended that much of the result claimed by psycho-analysis was due to adroit suggestion on the part of the analyst.

Dr. M. HAMBLIN SMITH pleaded for an unprejudiced examination of the claims of psycho-analysis. Psychology was the science which taught man about himself, but it dealt shrewd blows at his self-esteem. Freud's hypothesis went far beyond the limits of any system of therapeutics; it dealt with the normal as well as the pathological. He knew people who had been freed, by psycho-analysis, of phobias and of obsessive practices.

Dr. E. MAROTHEU said the great question was whether results were obtained by psycho-analysis which were not procurable by other means of treatment. After twenty years of experience and watching he remained in doubt on the point. At the present time he believed that truly free association was hardly ever obtainable; patients' associations were largely directed by what was obviously expected of them. What was most needed was an unprejudiced record of changes in patients seen before and after the process by people who were not professed and practising psychoanalysts.

Dr. CRICHTON MILLER also examined the subject in some detail, and declared his belief that the method was coming into use more and more.

Professor G. M. ROBERTSON said he regarded Freud as one of the greatest psychologists and one of the greatest discoverers the world had produced; no man could strike out an entirely new line without making mistakes. He spoke, not as an expert psycho-analyst, but as one who tried to take a detached view.

Dr. M. A. ARCHDALE said he preferred intentionally suggestive treatment. He asked whether, when the psycho-analyst obtained a cure, it was always because he had discovered the patient's disturbing complexes.

Dr. T. A. ROSS took the same view on the subject as Professor Robertson. He objected to the dictum that only those should carry out psycho-analysis who had themselves been subjected to it.

Dr. Potts, in a brief reply, dealt with the points raised.

#### THE ANNUAL DINNER.

The annual dinner took place at the Victoria Hotel, Northumberland Avenue, when a large number of distinguished people were present to support the President.

The toast of His Majesty the King having been loyally pledged, Dr. J. G. SOUTAN proposed "The London County Council," coupling with it the name of Sir George Hume, J.P., M.P., the chairman of the L.C.C. He said the functions and activities of that body were so numerous and varied that they made appeal to every special interest.

He pictured how the subject might be dealt with by a speaker from a number of special points of view—that of the historian, the sanitary engineer, the educationist, the architect. However viewed, those activities could be interpreted as a desire to give effect to the teachings of medical science. He referred in feeling terms to the loss the association and the profession had sustained by the death of Sir Frederick Mott, and to the great work he did in the special sphere covered by that body. He believed the beneficial results brought about by the Maudsley Hospital, in the founding of which Sir Frederick took an active part, would result in legislation being brought forward. He hoped the L.C.C. would continue to be fellow labourers with the profession for the still further improvement of the people.

Sir GEORGE HUME, in the course of his reply, said he had found, in his present position, that it was safer to listen than to speak, though he was glad to report that since the Council had entered into the occupation of its new home the relations of its members to one another had been much more harmonious than in former times. He was proud that the L.C.C. had on its staff men whose achievements made them known over the whole world. He concluded by congratulating the association on having been granted a Royal Charter.

Dr. R. PERCY SMITH submitted the toast of "The Universities and Royal Colleges," and, after speaking of the various ancient and modern universities, referred to the granting by several of them of the diploma in psychological medicine.

Professor G. M. ROBERTSON, P.R.C.P.Ed., in responding, gave an historical survey of the university teaching of psychiatry from 1923 onwards, and mentioned incidentally the establishment by William Tuke of The Retreat at York in March, 1792, six days after a requisition had been lodged by Admiral Duncan for a mental hospital at Morningside, Edinburgh.

Dr. WILLIAM BROWN, Wilde reader in psychology, Oxford, also replied. He referred to a certain university where it was not regarded as good form to be seen working, hence it was usual for men to read hard in the long vacation—that was why it was made so long. But the matter was quite different when one came to London University, where one needed an iron nerve to get through the examinations. He pointed out the great service to a man of having a system of philosophy to guide him, and discouraged the idea that any line of research and endeavour could be entirely "academic."

Dr. BEDFORD PIERCE proposed "The Royal Society of Medicine and the British Medical Association" in terms of appreciation of the work those bodies were doing for the benefit of the profession. He blended this sentiment with that of sympathy for those responsible for carrying on that work, as they must have great difficulty sometimes in satisfying everybody. He counselled every doctor to read carefully the *Handbook for Recently Qualified Medical Practitioners*. He had a special word of praise for the editors of the medical journals and the way in which they carried out their duties, though he thought there were few articles published in them which would not be the better for being cut down to half, or less, of their length.

Sir STCLAIR THOMSON, for the Royal Society of Medicine, kept the company in continual merriment by his narratives and topical sallies.

Sir DAWSON WILLIAMS, replying for the British Medical Association and its JOURNAL, made special reference to the recent death of Sir Frederick Mott, an old friend of his own, whom he regarded as a man possessed of quite exceptional qualities, who applied to this most difficult realm of medicine a scientific precision and thoroughness which was quite out of the ordinary, and was a very sincere believer in the possibilities of improving the human race.

Sir FREDERICK WILLIS (of the Board of Control) proposed the toast of "The Guests," coupled with the names of the Right Hon. Hugh Macmillan, K.C. (Chairman of the Royal Commission on Lunacy and Mental Disorder), and the Bishop of Southwark.

Sir HUGH MACMILLAN replied in an eloquent speech. Referring to the imminent appearance of the report of

the Lunacy Commission, he declared, amid laughter, that he was shortly starting on a voyage to Canada to escape the criticism with which it might be met. He paid a warm tribute to the medical profession for the great assistance which every member of it who was asked gave to the Commission during its sittings, and said that the report represented a sincere effort to assist the profession, and this special department in particular, in its noble task.

The BISHOP OF SOUTHWARK also replied.

Sir ARTHUR ROBINSON, K.C.B., proposed "The Royal Medico-Psychological Association," which, he said, was approaching its centenary, full of influence, power, and wisdom; he conveyed the good wishes of the Minister of Health to the association and the profession for success in its great task. With regard to the coming report of the Lunacy Commission, he had never seen, in all his experience, a commission so ably presided over as was this, and he had nothing but praise for the way Sir Hugh Macmillan did his work.

The PRESIDENT (Colonel Lord) replied, making mention of hospital clinics for early mental disorder, and the high aim of the mental hospitals of the country.

## AMERICAN HOSPITAL FINANCE AND ADMINISTRATION.

### LESSONS FOR BRITISH VOLUNTARY HOSPITALS.

As already mentioned (April 24th, p. 740), Mr. A. G. E. SANCTUARY, M.A., administrator of the Radcliffe Infirmary, Oxford, recently read a paper to the Oxford Division of the British Medical Association, describing certain aspects of the administrative policy and financial methods of American general hospitals which he thought should be imitated by British voluntary hospitals for the benefit of the public, the improvement of the service they afford, and the relief of their financial embarrassments.

America, Mr. Sanctuary said, possessed a complete and comprehensive system of hospital service which dealt with every section of the community at a cost varied to suit the pocket of each member of it. The accommodation and equipment were, he thought, on the average better than ours, and afforded the accommodation the public demanded. This was because the hospitals were not continually struggling to avoid bankruptcy.

One reason, but not the only reason, was the amazing prosperity of the nation, but there was, he thought, quite enough spare money in England to pay for a complete and comprehensive hospital system. He urged the managers of our voluntary hospitals, with the support of the medical profession, to undertake the in-patient treatment of every section of the community, and thus enlist the sympathy and financial support of every class, instead of confining their attention to the one class which cannot pay for itself.

It was well known, he said, that plans were in existence for the replacement of the voluntary system by some form of State-controlled hospitals; the case for this change relied mainly upon the fact that the present system failed to produce enough beds. It must be admitted that owing to lack of funds the needs of the community in the way of institutional treatment were at present inadequately met. First, there were not enough beds in the voluntary hospitals to take in the greatly increased number of patients who had a moral claim to treatment in free or partially free wards and could only afford to pay a fraction of the actual cost of their treatment, and by common consent could not pay an adequate fee to the physician or surgeon who attended them. Secondly, there was a very large class for whom no suitable provision was made and who consequently drifted into hospital wards and added to the congestion there. This class would be able to pay an adequate fee for board, lodging, and nursing, and for the use of the hospital's special equipment as they required it, and also a modified fee to the doctor, especially if they did so by an insurance scheme. Thirdly, there were the well-to-do classes, who had been content hitherto to pay large and often exorbitant fees for accommodation in nursing homes which did not contain a quarter of the equipment considered necessary for the treatment of the poor in the

voluntary hospitals. They were even content in emergencies to undergo operations in their own homes under conditions which would not be tolerated in a hospital, because no nursing home accommodation was available or because the charges were so high. It was certainly very greatly to the credit of this class that they should so long have continued to find large sums of money for the establishment and equipment of hospitals from which they were themselves debarred, in spite of the fact that they could get nothing so good outside. The problem of providing all three classes with adequate institutional accommodation in times of serious illness at a cost which collectively they could afford to meet could, he believed, only be solved if treated as a whole, as had been done in America. He continued as follows:

The quickest and most economical way of providing large-scale, perfectly equipped hospital centres for the treatment of every class is by extending the existing voluntary hospitals where a large part of the necessary equipment and staff already exists and among whose committees and medical, nursing, and lay staffs most of the hospital experience and tradition of the country are to be found.

The maintenance of such hospitals would not, I am inclined to think, present nearly such great difficulties as are faced under our present system. It has been proved that by organized weekly contributions of various kinds the poorest section of the community can pay from one-half to two-thirds of the actual cost of their treatment, the remainder being made up by charitable donations. The next class of patient, with incomes varying, say, from £300 to £750, could by means of insurance easily cover the cost of their treatment and doctors' fees, and leave a balance of profit to the institutions treating them, whereas at present they are driven into beds which are meant for the use of a poorer class, and pay less than they can afford. A smaller percentage of this class would require institutional treatment, because their home conditions are more suitable for treatment of certain illnesses than are those of the poorest class. Insurance schemes are already in existence which cover their policy-holders against the cost of specialists' fees and of nursing homes up to a certain maximum—a very much higher maximum than they are in a position to pay without the help of such schemes. These schemes would, I think, be readily joined if only the right sort of accommodation were provided, and it can only be provided at reasonable cost by the existing voluntary hospitals. The results of this extension of the present voluntary system would be:

(1) A large and deserving section of the population would be relieved of great anxiety and in some cases of severe economic distress, as they would be able to avail themselves freely of proper hospital equipment when they needed it without either crippling themselves financially or taking advantage of the voluntary hospitals and their honorary medical staffs.

(2) Their private doctors would be relieved of anxiety on their behalf and would not be placed in the invidious position of having to advise them to make use of accommodation and voluntary services, which they greatly dislike using and which is already insufficient for its proper purpose. They would also, under such a scheme, I hope, be able to continue to attend their patients in hospital to the same extent as they now do in nursing homes.

(3) The specialists would receive adequate payment for the work they do instead of doing it for nothing.

(4) The hospitals would receive a regular income, a part of which would be available for the upkeep of their special departments and overhead charges. Their ordinary ward beds would be relieved of pressure. They would, moreover, have enlisted the direct sympathy and help of a very large class, who at present are very little interested in hospital matters. The medical profession has already accepted the principle of dealing with this class in hospital by making use of wards in cottage hospitals for their private patients.

I think both hospital managers and doctors are generally agreed that an extension of our voluntary hospitals is desirable, but I do not think that this extension goes far enough. The people who have hitherto subscribed most of the money for the building and equipment of the hospitals are not satisfied on the whole with what they are getting in the way of institutional treatment. If the voluntary hospitals were prepared to offer them what they want in the way of first-class nursing-home accommodation, and to put at their service the whole of the equipment of their special departments, operating theatres, resident and nursing staffs, and so on, I feel sure that their generosity would be greatly stimulated, particularly in the case of the large and influential class of professional and retired men who just manage to pay their way in times of serious illness, but who have nothing left over for the support of charitable institutions. One has heard such people say over and over again that they wished they could go to a hospital when they are really ill, and that their servants' families get a better chance in emergencies than they do. It is obvious that the delay and discomfort involved in getting hold of the

nurses, the specialists, the x-ray photographs, or whatever may be needed in a particular case, would be obviated if their private doctors could send them to a large medical centre where all the specialists and all the necessary equipment were concentrated.

Rich Americans have been quick to recognize this, and have found the necessary money to build wonderfully equipped hospitals containing large blocks in which there are rooms varying in luxuriousness to suit the individual, and of course the price varies. They pay the hospital fees for the use of operating theatres, special departments, and special nurses if they want them, and they pay their doctors privately with the exception of the resident medical staff.

This arrangement seems to me excellent from the point of view of everyone concerned. From the well-to-do patients' point of view because they can obtain every luxury and comfort to be found in an expensive nursing home, combined with the use of equipment and organization which can only be found in a large general hospital, and with the services of a resident medical staff. From the poor patients' point of view because there will be less difficulty in finding the necessary funds for keeping the hospitals up to date and for perfecting the service and equipment; they will have better hospitals and more beds, because there will be more money to provide them.

With great diffidence I suggest that from the general practitioner's point of view it is excellent, because by sending his emergency cases to a fully staffed and equipped hospital he will be relieved of a thousand anxieties. Instead of having several really severe cases on his hands at long distances apart from one another and from his own home, he will have them concentrated in one place surrounded by every appliance and instrument that can be needed, and with a qualified medical man on the spot to carry out his instructions. He will no longer have to find nurses for his patients at all hours of the day and night, and be called out to visit them perhaps unnecessarily. He will only be called upon to give instructions as to treatment to a properly trained staff, and they will see that his instructions are carried out intelligently. I cannot help feeling that when every class has acquired the habit of going to a hospital when very ill the life of a doctor will become far more enjoyable, with reasonable hours of leisure and nights of comfortable sleep such as are enjoyed by other members of the community.

The same arguments apply to the specialists. They will spend far less time in motoring from place to place to carry out their work under exhausting and unfavourable conditions. Most of their work, with the exception of consultations, will be carried out in the hospital rooms and theatres and departments with ample equipment and a staff which understands their methods. They will in some cases be freed from the trouble and expense of providing apparatus in their own homes and of maintaining it there, and will have the satisfaction of employing for the benefit of their private patients the very expensive apparatus and buildings which they themselves have advised their committees to provide for the benefit of their poor patients.

From the hospitals' point of view the arrangement would mean freedom from financial worry, and the ability to produce a service which will not be cramped, either as regards its quality or its extent, by a lack of funds. The hospitals will be serving the whole community, and collectively the community will in return provide ample funds.

A further great advantage from everybody's point of view would be that the whole of the medical profession in a district would be brought into close contact with the hospital, which would consequently become a sort of continuous graduate school and a centre for the exchange of medical knowledge and experience.

I was staying last summer with an American physician on Long Island, where the population is increasing very fast. A hospital of about eighty beds was wanted in a small town there, and when I arrived they had just issued an appeal to build it. In a few weeks they had raised £300,000. So far as I could make out everyone subscribed as a matter of course in a businesslike sort of way, because everyone, rich and poor alike, realized that the time might come when they themselves would need hospital treatment, and therefore it was a question of common sense to provide the best hospital possible. Maintenance in America seems to be still easier. The expenses of the patients who cannot afford the whole of their cost is met by the profit made by treating the rich. A man who can afford it may have a beautiful tiled bathroom, and even a sitting room for his relatives next door to his own; these cost practically nothing to maintain, but the rich man may like to have them when he is ill, and certainly will not mind paying a few guineas a week extra for them. This is clear profit to the institution, which consequently prospers and improves in many ways. It makes it possible to improve the diet of the poor patients, to increase the salaries of the nursing staff, and so to attract more and better brains to the profession, and so on.

In fact, there is no end to the improvements that could be made if the committees had enough money, and I believe the money would be forthcoming if doctors and hospital managers combined to give the public what they want on the lines I have suggested. One often hears English business methods criticized on the ground that many firms are content to go on turning out certain articles, which they have produced for generations, without paying enough attention to changes in fashions and customs, with the result that by slow degrees their prosperity becomes less and less. I suggest with the greatest respect that this criticism might fairly be levelled against hospital managers and their staffs, and against the whole medical profession who have grown up under the voluntary hospital system. The economic conditions of the country have changed very greatly, but the voluntary hospitals are still clinging to their old traditions and are trying to limit the scope of their work within traditional boundaries. The public are trying their best to fit themselves in with the old system because they respect it and have a very real affection for it, but during the past two or three years friendly criticisms of the system and demands for its extension have been greatly on the increase.

I sincerely hope that the medical profession will combine with the hospital managers to expand and remodel the existing system of institutional treatment to suit the changing needs of the public, before the whole matter is taken out of their hands by purely commercial bodies, who will be prepared to undertake the paying side of the work as a profit-making concern, leaving the remainder for the voluntary hospitals to deal with under conditions which must become increasingly difficult as the various forms of treatment become more elaborate and expensive.

If the hospitals, starting as they do with fine equipment and buildings, and possessing great experience, will respond to what I think are the wishes of the public, they will put themselves in a strong position financially, and by a wise use of their money will become such an efficient as well as indispensable feature of the nation's life that their continued existence will be assured.

## England and Wales.

### VITAL STATISTICS.

THE Registrar-General's *Statistical Review* of England and Wales for 1924 has been issued. The number of deaths (473,235) is the smallest registered since 1867, when the population was only 56 per cent. of that estimated for 1924. They correspond to a rate of 12.2 per 1,000 of the estimated population, but when standardized this rate is reduced to 10.7. The standardization was effected by comparison with 1901 when the population included relatively few infants and old people; it formed, therefore, a standard exceptionally favourable to low mortality and accordingly yielded comparatively low standard rates all round. To correct any wrong impression thus produced and to provide standard rates comparable with those of other countries the standards recommended by the International Statistical Institute were used, when the rate was increased from 10.7 to 12.0 per 1,000. The standard rate of 10.7 was less than any returned prior to 1923, when the low record of 10.3 was reached. The increase of mortality, which applied equally to each sex, occurred entirely in the first quarter of the year, when the death rate rose from 13.2 per 1,000 in the previous year to 16.6. The rate for the second quarter was lower than for any of the previous nine years, except 1921, and those of the third and fourth quarters were the lowest yet recorded. The excess in the first quarter occurred chiefly in March and was largely due to influenza, but the rate was high for a number of other diseases also, and it would appear that the conditions during March were such as to hasten the advent of death when impending from many causes not otherwise affected by season. The rate of infant mortality was 75 per 1,000 births, and was the lowest recorded, except in 1923, when it fell to 69. In a section on the distribution of infant mortality it is shown that the rates for the county boroughs and for the North of England are, as usual, in considerable excess, the highest rate being 99 for the northern county boroughs, and the lowest, 51, in the rural districts of the south. Taking the country

<sup>1</sup> New Annual Series, No. 4 Text. H.M. Stationery Office, London, Manchester, Cardiff, and Edinburgh, or through any bookseller. Price 5s. net.

as a whole, the fall of 6 per cent. as compared with the preceding quinquennium was accounted for by a decline in the number of deaths attributed to diarrhoea, congenital debility, and convulsions. There was an increase from bronchitis and pneumonia. The reduction of mortality at ages 1 to 5 has been greater than in that of infants. As was pointed out in the report for last year, this is the period of life at which susceptibility of mortality to environment is greatest, so it is probable that improvement in the conditions under which the children were living has been the main factor in bringing about this remarkable change. For this improvement the fall in the birth rate may be largely responsible, but if so it "cannot be expected to continue for long at the recent rate, for the birth rate, though it may continue to fall, cannot long do so at the present rate consistently with national survival." These seem to be the chief broad conclusions the Registrar-General draws from the statistics at his disposal. We hope to recur to the report later on.

#### THE CARE OF CRIPPLES IN HERTFORDSHIRE.

The annual meeting of the Hertfordshire branch of the British Red Cross Society was held, through the kindness of the Hon. A. Holland Hibbert, in the beautiful grounds of "Munden," near Watford, on July 16th. Hertfordshire bore its part worthily in Red Cross service during the war and did not allow its organization to fall into decay after the stoppage of actual warfare. In 1919 the energies of its Voluntary Aid Detachments were diverted largely to the service of a number of massage clinics which were established for the benefit of ex-service men, and their scope was afterwards widened to include the treatment of civilians of all ages.

Advantage was taken of this organization when the care of cripples came to be considered, and the six orthopaedic centres which now exist in the county work side by side with the massage clinics, of which there are now nine, and with the after-care centres at Hertford and Hoddesdon. The members of the Voluntary Aid Detachments staffing these centres are now so efficient that the latter are equivalent to out-patient departments, where all sorts of plaster work are carried out, and almost the whole treatment, except that requiring cutting operations, for which patients are admitted to the Royal National Orthopaedic Hospital under the honorary visiting surgeon, Mr. S. L. Higgs. Hertfordshire is exceptionally well supplied with railway communications from south to north, but very badly off for transit from east to west. In consequence it is found that London, where the Hertfordshire County Council meets, is the most convenient centre for the whole county, and the Royal National Orthopaedic Hospital, with its country branch of 118 beds at Brockley Hill, is more conveniently situated than would be any possible hospital placed near the geographical centre of the county. The present arrangement has the advantage of securing that the patients are in the care of the same orthopaedic surgeon from first to last. During the year ending March 31st, 1926, there were over 21,000 attendances at the massage clinics; a number of these patients were no doubt orthopaedic cases, and there were 1,458 attendances at the orthopaedic centres; of these, 335 were new cases, and on them 338 reports were made to the medical practitioners in whose care the patients had been. This system leads to improved co-operation as well as efficiency, and obviates possible causes of friction. The annual report, while it shows good progress in the efficiency of the Hertfordshire branch, demonstrates the need of more financial support. Watford, in particular, which is the most populous of all the centres, is not self-supporting, but draws upon the county funds. The Hon. A. Holland Hibbert, in a humorous and effective speech at the meeting, appealed forcibly to Watford to remove this stain from its reputation.

After the business of the annual meeting Mr. Muirhead Little, F.R.C.S., addressed the members on the cure and care of cripples generally, and on the work of the Central Committee. He pointed out that, although crippling as the result of tuberculosis and rickets might be expected to decrease perhaps rapidly, it was far otherwise as regards infantile paralysis. For aught that was

known, this country might suffer from an epidemic comparable to those that had occurred in Sweden, Germany, New England, and, above all, in New York. In the case of such a misfortune, the county clinic organization would be invaluable, for it was susceptible of rapid expansion with a minimum of friction. The main points to be attended to in any district scheme were: (1) that every case of incipient crippling, whatever its cause, should be detected and at once treated at a clinic; (2) that there should be no delay in gaining admission to hospital of cases that required hospital treatment; (3) that after treatment in hospital or clinic was complete every case should be kept cured by the necessary care at a clinic; (4) that during hospital treatment education should be carried on; and (5) that industrial training should be available for all cripples over school age. The Central Committee for the Care of Cripples had obtained for a scheme of this kind the provisional approval of the Ministry of Health. It suggested a special committee in each orthopaedic area containing representatives from the hospitals and clinics, who would know the capacity and limitations of the cripples from the surgical point of view, together with representatives from the Juvenile Employment Exchange, employers, and trade unions, who would know local trade conditions and appointments. Hertfordshire was far advanced along the right line, but for a certain number of cases whose home surroundings were not good a convalescent institution was needed. It should be an open-air home, of simple and therefore cheap design and construction, as might be studied in the Cripples' Hospital at Coombe Park, near Bath; to begin with it need have not more than twenty beds. The address of the Central Committee is 117, Piccadilly, W.1.

## Scotland.

CHAIR OF OBSTETRICS AND GYNAECOLOGY IN EDINBURGH. DR. ROBERT WILLIAM JOHNSTONE, C.B.E., M.A., M.D., F.R.C.S., has been appointed professor of midwifery and diseases of women in the University of Edinburgh, in succession to Professor B. P. Watson, who was recently appointed to the corresponding chair in Columbia University, New York. The new professor is a son of the late Rev. Professor Robert Johnstone, D.D., of the United Free Church College, Edinburgh. He received his early education at George Watson's College, Edinburgh, and graduated with honours in medicine at Edinburgh University in 1903, subsequently pursuing post-graduate studies in Vienna and Prague. From 1906 to 1919 he was assistant to the professor of midwifery in the university. During the war he was successively surgeon to the Royal Victoria Red Cross Hospital, a surgical specialist in France, and later held a post in the Ministry of National Service in London. Returning to Edinburgh in 1919, he became Dean of the School of Medicine of the Royal Colleges, and up to the time of his present appointment was physician at the Royal Maternity Hospital and assistant gynaecologist in the Royal Infirmary, Edinburgh. He has also conducted a successful class as lecturer on midwifery and gynaecology in the School of Medicine of the Royal Colleges at Edinburgh. Professor Johnstone has made numerous contributions to the current literature of his subject, upon such aspects as "The pathology of pelvic infection," "Scopolamine and morphine in labour," "Unsolved physiological problems in gynaecology and obstetrics," and "Results of operative treatment of intrinsic dysmenorrhoea." The work by which he is best known is his valuable and highly successful *Textbook of Midwifery*, published in the Edinburgh Medical Series, which has now reached its fifth edition. Great satisfaction is expressed in Edinburgh that the curators of the chair have selected for the post an Edinburgh man, who may be trusted not only to be familiar with, but to enhance the traditions of, the chair previously occupied by Hamilton, Simpson, and Croom.

#### HOMES FOR DISABLED EX-SERVICE MEN.

The Liberton Settlement for Disabled Sailors and Soldiers at Kaim's Crossroads, near Edinburgh, established by the Scottish Veterans' Garden City Association, was

formally opened on July 3rd by Lord Provost Sir William L. Sleigh. The first block of the settlement consists of a substantial building containing five houses, each house including a living room and small kitchen downstairs, with two bedrooms and other accommodation upstairs; a generous amount of garden space is allowed to each tenant. Lord Salvesen, chairman of the association, who presided at the opening ceremony, said that in the eleven years since the association had commenced to ask for subscriptions nearly 200 houses for disabled men and their families had been provided. These houses were at present inhabited by something like 1,000 people, so that the association had done something towards both solving the housing problem and repaying their debt of gratitude to the men who had suffered most in the war. The Lord Provost, in declaring the settlement open, said that the work of the association had extended all over Scotland, and the present was the eighteenth settlement where disabled men could live in comfort and bring up their families amidst healthy and pleasant surroundings. Although no actual rent was charged for the houses the occupant was called upon to pay the rates and taxes and other oncosts. He believed that no other country was in possession of a scheme such as this. It was mentioned that the cost of each house was now about £600.

## Correspondence.

### CARCINOMA OF THE PROLAPSED CERVIX.

SIR,—The JOURNAL of July 3rd (p. 12) contains an interesting Memorandum on carcinoma of the prolapsed cervix by Mr. N. A. Macleod, in which he remarks that prolapse and cancer of the cervix, though individually common in the same class of cases, very rarely coexist. He also suggests that cancer is less liable to develop in the prolapsed cervix than in the non-prolapsed.

I have been wondering whether the conjunction of the two conditions is really rare. When cancer is found, co-existent prolapse is often ignored and the case is classified and recorded as one of cancer. Again, cancer of the cervix of the common columnar-celled type soon extends into the parametria and fixes the uterus. The majority of cases are only seen after this has occurred, when pre-existent prolapse has already been more or less cured by fixation, so to speak, and is no longer obvious. In cases of the stratified squamous type, like Mr. Macleod's Case 1, fixation of the uterus occurs much later than in the common type.

There are other conditions which are seldom seen together with prolapse, a notable example being complete rupture of the perineum. Pelvic cellulitis is another good example. It fixes the uterus by inflammatory infiltrate in the parametria and thus it prevents prolapse in some cases and cures it in others.

The first case of cancer of the vagina I ever saw was in a procidentia under the late Dr. Lloyd Roberts. It is figured in my handbook of *Diseases of Women*. I have always taught that one should operate for prolapse by the vaginal route, and should try to exclude cancer by exploring with a curette both the cervical canal and the uterine cavity. During this routine preliminary examination I have three times found early unsuspected cancer of the body of the uterus, and more frequently cancer of the cervix. On each occasion a radical operation has, of course, been done instead of the plastic operation.

High amputation of the cervix is an essential part of my own operation for uterine prolapse, which thus has the advantage that in addition to curing the prolapse it frees the patient from the risk of the subsequent development of cancer in the cervix. This risk remains after operations like ventral fixation.

Early cancer originating within the cervical canal may escape detection by the curette. Only last week the senior resident at St. Mary's Hospitals, Manchester, sent to the laboratory a cervix he had removed for prolapse, and received a report that on section it showed distinct evidence of carcinomatous change. Thus it is desirable that every suspected cervix removed for prolapse should be submitted to microscopic examination. If early cancer is

found the surgeon will decide between radical operation and the use of radium according to the circumstances of the case.—I am, etc.,

Manchester, July 15th.

W. E. FOTHERGILL.

### RHEUMATIC HEART DISEASE IN CHILDREN.

SIR,—I would like to congratulate the Science Committee, and through it the Association in general, on the excellent report on rheumatism and heart disease in children. It is very typical of the English character to depreciate our own efforts and laud those of our neighbours, and whilst one recognizes perfectly and congratulates very heartily the Americans on their progress in supervision of children suffering with cardiac lesions, self-depreciation can be carried a little too far, and I am quite sure that the report gives a needlessly pessimistic view of the stage to which treatment of this condition has arrived in England. Whilst this may be good propaganda, it may still be bad policy.

The investigations with regard to treatment seem to have been made through the school medical officers, whose interest in the subject may be gauged by the percentage of replies. Possibly this line of investigation was adopted advisedly, but it seems strange that the authorities actually treating—as distinct from tabulating—the largest number of sick children should have been so carefully ignored. Of course, at present it is highly improper to suggest that boards of guardians ever did anything right, more particularly as regards their work for the sick; but possibly reference to the work of the Manchester Board of Guardians with regard to its attitude towards its sick children may be illustrative of what is taking place more or less throughout the country, though it be not widely advertised.

The essentials of treatment as laid down in the memorandum are: (1) provision for prolonged treatment, including rest in bed for an indefinite period, with mental stimulus and suitably graded finger work; (2) adequate attention to septic conditions, particularly of the mouth and tonsils; and these conditions are entirely met by the scheme at present worked by the Manchester guardians. Five years ago the dentist visiting Booth Hall Infirmary for Children began to examine the mouths of children suffering particularly from carditis and tuberculosis of any type. He renders these as free from sepsis as he can at the earliest possible moment after their admission. Three years ago the aurist began to pay similar attention to the throats and noses of these children, and enucleation of tonsils is carried out by him when considered needful. Provision is made at the above-named hospital for treatment as prolonged as may be necessary, and when cases become ambulatory they are, on the recommendation of the visiting physician, Dr. Hugh T. Ashby, recommended for transfer to one of two convalescent homes. In one the children are up practically all day, and go to the school provided in the home until such time as Dr. Ashby considers they may be transferred home. In the other, dealing with more serious cases, rest and exercise are carefully regulated. Between these three institutions there is complete co-ordination. Children are transferred from the convalescent homes to the hospital, or vice versa, when occasion requires, by means of motor ambulances. On a child being discharged home the Invalid Children's Association is notified of the fact, and the chain of supervision becomes as complete as can be arranged.

The guardians are of opinion that they have provided as complete and efficient a scheme as need be desired, but they certainly do not imagine that they are the only authority endeavouring to meet the very serious needs of this difficult type of case.—I am, etc.,

J. D'EWART,

Medical Superintendent, Booth Hall Infirmary.

Manchester, July 11th.

### THE PROPHYLACTIC VALUE OF SCARLET FEVER ANTITOXIN.

SIR,—Dr. E. H. R. Harries, in his interesting communication to the BRITISH MEDICAL JOURNAL of July 17th (p. 134), refers in his concluding paragraph to the pro-

duction of active immunity to scarlet fever in the staff of the Birmingham City Hospitals. The following figures, having reference to this subject, are of interest as indicating the apparent result of active immunization at the Fazakerley Hospital.

| Year.                          | No. of new proba-<br>tioners entered. | No. who contracted<br>scarlet fever. |
|--------------------------------|---------------------------------------|--------------------------------------|
| 1921                           | 39                                    | 4                                    |
| 1922                           | 26                                    | 2                                    |
| 1923                           | 47                                    | 2                                    |
| 1924                           | 66                                    | 10                                   |
|                                |                                       | (1 fatally)                          |
| January 1st to June 30th, 1925 | 20                                    | 1                                    |
| July, 1925, to July, 1926...   | 54                                    | 0                                    |

Active immunization was begun in July, 1925.—I am, etc.,

C. RUNDLE,

Medical Superintendent, Fazakerley  
Hospital, Liverpool.

July 17th.

## Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

### Registration of Nursing Homes.

THE report of the Select Committee of the House of Commons on the Registration of Nursing Homes was published on July 19th.

#### RECOMMENDATIONS.

Its recommendations are thus summarized :

- (i) That . . . . . scheme of registration and introduced at an early date.
- (ii) That . . . . . should be county councils
- (iii) That . . . . . ay well be empowered to upon which both doctors and nurses shall have some representation.
- (iv) That the duties of inspection shall be carried out by medical officers of health with the assistance of other technical officers.
- (v) That inspection shall be limited to the general suitability and organization of the home, and shall not embrace any inquiry into the medical records or private affairs of the patients.
- (vi) That the definition of the term "nursing home" shall be made wide enough to include all types of nursing homes, including maternity homes.
- (vii) That certain publicly controlled institutions shall be expressly excluded from the scheme.
- (viii) That . . . . . authorities may exempt certain charitable . . . . . periods of time.
- (ix) That . . . . . shall not be exempt on the sole ground . . . . . lical practitioner resident in or in actual control of a home.
- (x) That appeals against the refusal or cancellation of registration may be made to a referee appointed by the Minister of Health.
- (xi) That, in spite of existing legislation in regard to maternity homes, all nursing homes, including maternity homes, shall be brought under one comprehensive scheme.

The Committee recommend that, subject to the provisional exemption by the supervising authority of existing homes at present controlled and staffed by unqualified persons, and to possible exemptions in special circumstances, it should normally be a condition precedent to registration that the matron or other person in charge of the nursing in any registered nursing home be a fully qualified nurse; and that, if and when nursing becomes a more popular and better paid profession, the extension of this condition to a certain proportion of the staff employed in the home will also become desirable.

#### COMMENTS ON EVIDENCE.

##### Nursing Homes Maintained by Doctors.

With regard to the claim advanced by the British Medical Association for exemption of doctors who receive patients for treatment into their private homes, the Committee say :

Many doctors take in single patients for treatment in their private houses; frequently such cases require no actual nursing but merely normal home life and the sympathetic companionship of intelligent persons. It is submitted by certain witnesses at the term "nursing home" cannot properly be applied to cases of this type and that registration is not required, would do no good, and would be strongly resented by the medical profession. There are a number of nursing homes and private hospitals directly controlled by medical men, and often having a medical officer resident therein. Strong representations have been made by the medical profession that, although there would be no objection to simple registration, such homes, particularly those with a resident medical officer, should be entirely exempt from inspection. If registration is considered necessary, it is suggested that the registration authority should place on the register any home controlled by a qualified medical practitioner who can submit to them certificates from two recognized medical men that he is a fit and proper person for the conduct of such an establishment. This system, it is pointed out, is already in operation in certain areas which have obtained powers for the registration and inspection of maternity homes. The Committee feel that there is much to be said for this point of view, but,

on the other hand, they have had evidence put before them which indicates quite clearly that in certain cases there is very decided room for improvement in nursing homes under the direct control of a doctor. They feel that if an individual doctor decides, for purposes of gain, habitually to take in patients, whether into his private house or into a nursing home, he does so with the full knowledge that he is taking up a definite trade and entering into competition with other persons who have to comply with such regulations as may be enforced. Some medical witnesses have objected to the public display of the rules and regulations drawn up by the supervising authority, and to the exhibition of brass plates outside registered nursing homes. The Committee are opposed to any form of compulsion in this matter.

#### Inspection.

Discussing the evidence tendered to them the Committee say :

It has been strongly urged that inspections should be carried out by a qualified medical man, or woman, preferably by the medical officer of health or some similar officer on his staff and deputed by him. It has been pointed out that in many cases it would not be necessary to appoint special officers for the conduct of this work; in short, that it could be taken by medical officers of health in their stride. On the other hand, objections have been raised by a number of witnesses as to the ability of a medical man to inspect the efficiency of the nursing services and as to his capacity for criticizing the domestic arrangements of a home. It is suggested that a medical man is not trained in the art of nursing, and that he would be slow to criticize or interfere with such matters; further, that he would not be likely to detect with the same ease, if at all, minor irregularities in the domestic arrangements, which, although in themselves small, have a considerable cumulative effect upon the health and happiness of patients and nurses. A trained nurse, it is suggested, is the only person competent to inspect and criticize these details. (As stated in the summary, the Committee recommend that inspection should be by medical officers of health.)

#### Structural Deficiencies.

On the evidence presented the Committee are convinced that the dwelling house converted into a nursing home with its many structural deficiencies which cannot be overcome is, at any rate in acute surgical cases, a very poor and expensive substitute for the specially built, adequately equipped and staffed, hospital. It is, of course, true that at the present time there is a considerable demand for nursing home accommodation, and that in fulfilling this demand nursing homes serve a useful purpose, but development in the provision of accommodation for the paying patient should run more along the lines of the provision of specially built and equipped private hospitals and homes, and of the extension of the paying ward system in the existing big hospitals. The Committee note that the complaints from doctors who gave evidence were mainly directed to structural and sanitary defects in the buildings used as nursing homes, and to the lack of proper provision and equipment in regard to surgical cases.

#### Chronic Senile Cases.

With regard to chronic senile cases the Committee report as follows :

The Committee have been impressed with the urgent need for registration and supervision in that class of nursing home which caters for the poor senile chronic. It has been stated in evidence that it is impossible adequately to nurse and accommodate, in a private room, a patient under £5 a week. Unfortunately there exists a large class of elderly persons who although they are capable of making some payment are quite unable to find a weekly sum of this order. The Committee consider that the general application of registration and inspection will do much to alleviate the bad conditions and suffering undergone to-day by patients of this class, but they strongly emphasize their opinion that this change cannot be regarded as a cure for these evils, but merely as a palliative. They feel that the problem can only be properly solved by the reorganization of the Poor Law system, and by the provision of proper paying accommodation by local authorities to meet needs. It has been made abundantly clear to the Committee that the provision of accommodation for the nursing staff in nursing homes of all grades leaves very much to be desired.

#### Bills.

On the motion of Dr. Fremantle, on July 14th, the amendments made in the Midwives and Maternity Homes Bill in the House of Lords were considered in the House of Commons. The amendment providing that the embargo against unqualified persons acting as midwives should not apply to the education of medical students or midwives was agreed to. Another amendment provided that a supervising authority might grant an exemption to a hospital, or other premises for which a duly qualified medical practitioner there resident was responsible, or any hospital or institution not carried on for profit and not used mainly as a maternity home. It was under consideration when the debate was adjourned.

The House of Commons read the Land Drainage Bill a third time on July 14th. It had already passed the House of Lords, where Lord Bledisloe, for the Ministry of Agriculture, had pointed out that inadequate land drainage adversely affected public health and also produced diseases in animals.

The British Medical Association's Report on Rheumatic Heart Disease in Children.—Mr. Chamberlain stated, on July 15th, that the recommendations in the British Medical Association's report on rheumatic heart disease in children were substantially in accord with the suggestions in the chief medical officer's preface to the

Ministry of Health report on rheumatic diseases, published in 1924. Continuous attention was paid to them in deciding the administrative policy of the Ministry, which used all the pressure and influence it could bring to bear to secure the improvement of housing conditions which might cause rheumatic diseases in children.

**Motor Drivers.**—During the discussion on the estimate for the Ministry of Transport, on July 14th, Mr. Bromley asked whether, in view of the proposed introduction of coloured light signals for regulating road traffic, the Minister had made any provision to test motor drivers for colour-blindness; and Mr. Palin urged that driving licences should be granted only to applicants possessing satisfactory physical qualifications. Eighteen was young enough for the driver of a light motor vehicle, and 21 for a heavy lorry. He suggested also that the time for which a driver should be allowed to work ought to be limited, as was the case with railways and tramways. A fatigued driver was a danger to the public, and there ought to be prescribed periods of rest. In the course of his reply Colonel Moore-Brabazon (Secretary to the Ministry) said that the danger of dazzling headlights was becoming less every day. A vehicles bill about to be introduced would lay down standards for the weight of various types of vehicles. In reply to a question the Home Secretary said that during the first six months of this year the metropolitan police had taken out 3,000 summonses against motorists for excessive noise. The noise was due probably to inefficient silencers, particularly in the case of motor cycles. The question was being discussed between the Ministry of Transport and the Motor Cycle Manufacturers' Union. In answer to another question, the Minister of Transport said that complaints had been received with regard to the pollution of the atmosphere by steam-driven vehicles. The matter could be dealt with under the existing law, the enforcement of which was for the police.

**Indian Opium.**—The Home Secretary informed Mr. Ponsonby that 116,000 lb. of raw opium were imported into this country from India in 1925; 16,000 lb. were exported during the same year. The Indian opium retained in this country was used for the manufacture of morphine and other drugs and medicinal preparations. In five years 730 lb. of refined and 6,050 lb. of crude morphine hydrochlorate had been manufactured in India.

#### Notes in Brief.

Deaths from cholera registered during 1924 in Indian cities were: Calcutta, 1,250; Rangoon, 132; Madras, 96; Karachi, nil; Bombay City, 34.

Mr. Chamberlain told Mr. Kennedy, on July 15th, that he could not yet say which of the recommendations of the Royal Commission on National Health Insurance would be adopted by the Government nor when it would be possible to introduce the necessary legislation to give effect to them.

(To be continued.)

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

The following candidates have satisfied the examiners in both parts of the examination:

**DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.**—H. M. Ayres, J. L. Dunlop, Banaji Eshirajulu, N. E. Goldsworthy, Riad Abdel Noor Henein, \*Farid Hilmy, Wasfi Omar, \*Trilok Chand Pari, F. C. Tiobs, \*Abdul Wahid el Wakil.

\* Distinguished in the examination for Part II.

The following candidates have been approved at the examinations indicated:

**DIPLOMA IN MEDICAL RADIOLOGY AND** —  
Frances Dooley, H. Franklyn.

J.  
M.  
J.

... Constable A. T. Wood.

## Medical News.

A DINNER arranged by the London Association of the Medical Women's Federation was held at the Welbeck Palace Hotel, on July 15th, in honour of Dame Mary Scharlieb. The President, Dr. Christine Murrell, presided, and the health of the principal guest was proposed by her old friend and fellow student, Dr. Jane Walker, who spoke warmly of her personal qualities and professional standing. Dame Mary Scharlieb was over 40 years of age before she ever had a scalpel in her hand, and now, at 81, she was still operating with unimpaired judgement and skill. Dr. Walter Carr paid tribute, not only to the outstanding surgical ability of Dame Mary Scharlieb, but to her high character. All her friends would rejoice at the national recognition of her services, which were the more valuable because the love of her fellow creatures had prompted them. Lord Riddell pointed out that the British virtues of courage, pertinacity, and ability were here combined with charm of manner and an unusual and enduring vitality. Sir Alan Anderson praised the pioneer spirit that was an inspiration to all younger women,

and Lady Barrett, as dean of the London (Royal Free Hospital) School of Medicine for Women, spoke of the pride of all members of the school in the honour that had been conferred on Dame Mary Scharlieb. In reply, Dame Mary Scharlieb said that if life were a quest for happiness she had discovered how to achieve it in the love of God and of her friends. Among the guests present were Sir John Rose Bradford and Sir James Berry.

THE KING has been graciously pleased to confer the Territorial Decoration upon Lieut.-Colonel J. W. Craven, M.C., and Major Charles Douglas, both of the Royal Army Medical Corps.

A SCHEME for a general contributory system of pensions, supported by King Edward's Hospital Fund for London, has now been accepted by sixty-nine of the hospitals in London. It will include nurses in all branches of the profession, as well as those in hospital service.

THE Committee upon the Physiology of Vision, appointed by the Medical Research Council at the instance of the British Medical Association, has issued a report (H.M. Stationery Office, 2s. 6d. net) by Mr. R. J. Lythgoe, M.A., B.Ch., founded upon recent literature on the relation of illumination to visual capacities.

As announced last week, the post-graduate medical hostel at the Imperial Hotel, Russell Square, London, W.C., will be opened on Monday next, July 26th. There will be a dinner (5s.) at 8 p.m., and at 9 a meeting over which Dr. Alfred Cox will preside, when Sir D'Arcy Power will give an address on the hostel and its objects; ladies will be welcomed. On Friday, July 30th, at 9 p.m., a discussion on the difference between inflammation and hyperplasia will be opened by Sir G. Lenthal Cheate. All medical practitioners are invited to attend.

THE Fellowship of Medicine announces that the last of the demonstrations arranged for this session will be given by Mr. Dorrell at the Royal Eye Hospital, Southwark, on July 30th, at 3 p.m.; it will be open to members of the medical profession, without fee. In connexion with its intensive courses in medicine, surgery, and the specialties attention is directed to the formal lectures throughout the week at the Prince of Wales's General Hospital, Tottenham, at 4.30 p.m., which are open to members of the Fellowship. The West End Hospital for Nervous Diseases is providing weekly courses of lecture demonstrations until August 12th. Owing to unforeseen circumstances the intensive course at the Brompton Hospital for Chest Diseases has been cancelled. The entire clinical work of the hospital will be available, however, daily throughout the month to graduates on payment of the fee of 1 guinea. From August 18th to 28th the Queen's Hospital for Children will hold an all-day course, and the Queen Mary's Hospital has arranged an intensive revision course from August 23rd to September 4th. Practical courses in anaesthetics and courses in obstetrics and child welfare at the City of London Maternity Hospital can be arranged by the Fellowship. For full particulars as to details of these various courses inquiries should be made to the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE campaign for cancer research instituted by the University of Sydney was, according to an Exchange dispatch, formally launched at a meeting presided over by the Governor of New South Wales on July 14th. It is hoped to obtain £100,000; towards this amount £25,000 has already been subscribed.

THE house of the Royal Society of Medicine will be closed during August, but the library will be open on week-days from 11 a.m. to 6 p.m., except on Saturdays, when it will close at 1 p.m.

DR. ARTHUR CUSHNY, professor of materia medica and pharmacology in the University of Edinburgh, left estate of the value of £22,140, with net personality of £21,984.

THE Secretary of the Department of Scientific and Industrial Research announces that a licence has been issued by the Board of Trade to the British Food Manufacturers' Research Association, which has been approved by the Department as complying with the conditions laid down in the Government Scheme for the encouragement of industrial research.

THE seventh Congress of Italian Industrial Medicine will be held at Genoa from October 12th to 15th under the presidency of Professor G. B. Ramoino. Among the subjects to be discussed are individual conditions and organic changes in persons affected by electric currents, and workmen's dwellings. Further information can be obtained from the general secretary, Dr. Agostino Crosso, Via Frugoni 19, Genoa.

A POST-GRADUATE course in tuberculosis will be held at the Strasbourg Faculty of Medicine under the direction of Professors Canuyt and Vaucher, from October 10th to 25th. The fee is 200 francs. Further information can be obtained from Professor Vaucher, Rue de l'Université 22, Strasbourg.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

**EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London.*

**FINANCIAL SECRETARY AND BUSINESS MANAGER**

(Advertisements, etc.), *Articulate Westcent, London.*

**MEDICAL SECRETARY**, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumslough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

### QUERIES AND ANSWERS.

#### INCOME TAX.

##### *Production of Accounts.*

"A. P. L." was last year called upon to produce accounts in support of his income tax return. He employed an accountant, with the result that his return was found to be somewhat excessive, but his gain in tax was less than the accountant's fees. He has now been asked to produce an account for the year 1925, but wishes to avoid further expense.

\* \* We advise "A. P. L." to send in a statement, prepared and certified by himself on the same lines as the accountant's statements, with a covering note pointing out that, as the sufficiency of his previous returns was corroborated by the independent accounts last year, he is not prepared to incur the further expense of employing an accountant again.

##### *Cash Basis.*

"O. R." has been informed by his local inspector of taxes that in future the district commissioners of taxes "are not prepared to accept from professional men accounts which are on a cash basis only."

\* \* This question crops up from time to time, and the attitude of the authorities has generally been that they are prepared to accept cash accounts in normal cases, reserving their claim to press for an adjustment for the value of outstanding book debts when they are increasing in a marked degree. It is undeniable that in theory accounts should include such adjustments, but it is only in the case of rapidly growing practices or where a practice changes hands that they affect materially the income tax result, and undoubtedly an accurate adjustment (involving as it does the probable value of each outstanding debt) is almost impossible to calculate. "O. R." has the choice of three courses: (1) to lodge a formal request that his assessment shall be made by the Commissioners for Special Purposes instead of by the district commissioners, seeing that the latter seem to have prejudged the issue in his case; (2) to maintain his refusal and appeal personally to either of the two bodies of commissioners if his accounts are not accepted; and (3) to send in the figures for each of the three years forming the average, quoting (a) the nominal amount of outstanding debts at the beginning and end of the year, and (b) the figures at which, after a careful examination, he estimates their actual value.

### LETTERS, NOTES, ETC.

#### **SPIROCHAETOSIS ICTEROHÆMORRHAGICA.**

**DR. ANDREW BALFOUR** (Director, London School of Hygiene and Tropical Medicine, W.C.1) writes: I read with interest the paper on "Spirochaetosis icterohæmorrhagica in Norfolk" by Dr. Burton-Fanning and Dr. Cleveland, which appeared in the **BRITISH MEDICAL JOURNAL**, (July 17th, p. 103). The symptoms of the cases they record certainly simulate those of the condition formerly known as Weil's disease, even though the account of

the spirochaetal findings in the urine of Case IV does not appear to me to be quite convincing. My object, however, in writing is to draw the attention of the authors to a paper which they have apparently missed—namely, that by Hindle and Brown in the *Lancet* for August 22nd, 1925 (p. 372). This paper, entitled "Spirochaetosis jaundice in Great Britain," gives an account of two cases of the disease occurring in England which were undoubtedly associated with a small outbreak at a school in the Midlands. Hindle and Brown point out that there is some evidence that a mild form of the disease is widespread in this country. I note that the cases recorded by Drs. Burton-Fanning and Cleveland were all severe and that three of them ended fatally.

#### **UNRECOGNIZED SMALL-POX IN POOR LAW INSTITUTIONS.**

**THE** Minister of Health has issued a circular letter to guardians stating that his attention has been drawn to recent instances in which unrecognized cases of small-pox have been admitted to Poor Law institutions and have been the means of spreading the infection before their true nature was discovered. The Minister points out that the regulations in force require every person on admission to be examined by the medical officer, and he requests that the attention of the medical officer should be drawn to any skin eruption observed on admission or afterwards noticed by the nurses or attendants. He asks further that at the larger Poor Law infirmaries the attention of the junior medical staff should be directed to the importance of immediate consultation with the medical superintendent if a patient should exhibit symptoms which might be due to small-pox. He adds that in all cases of doubt concerning the diagnosis the medical officer should at once inform the medical officer of health and request him to see the patient.

#### **A FINE RIFLE SHOT.**

EVERYONE will have noticed the fine performance of Dr. F. H. Kelly in tying for the King's Prize this year at Bisley. Dr. A. M. HUMPHRY sends us the following list of prizes Dr. Kelly has won at Bisley in recent years:

Grand aggregate 1914, 1922, and 1923. All comers' aggregate 1922 and 1923. Service rifle championship 1914. Elkington aggregate 1923 and 1925. In the King's Prize Dr. Kelly reached the final stage in 1910, 1921, 1922, 1923, and 1925. He won the Bronze Medal in the first stage in 1922, and in 1924 was again in a leading position in the aggregates, but was unable to remain at Bisley for the later part of the meeting. He was third in the King's Prize last year, and this year won the Silver Medal in a tie shoot of three. In the final stage this year he was one of four who tied with 286; in shooting off he was beaten by 1 point by the winner, Mr. Arthur Fulton.

#### **THE AUTOMOBILE ASSOCIATION.**

AT the twenty-first annual meeting of the Automobile Association held at the Savoy Hotel on July 14th, Lord Donoughmore, one of the vice-presidents, was able to announce that the number of members of the Association now exceeded 300,000. The meeting was also memorable because, probably for the first time on record, four members arrived with a "grouse." Apparently these gentlemen were sympathizers with the general strike, and were annoyed that some minute portion of their subscriptions had been used to help in defeating it. Two of them spoke at great length and were admirable exponents of the art of drawing red herrings across the trail. They contended that the action of the committee in offering the assistance of the machinery of the association to the Government was *ultra vires*; but their resentment was not sufficient to permit them to accept a return on their subscriptions. It is curious to note that one of the speakers Mr. W. J. Brown, is described as the secretary of the civil service clerks' trade union. The protesting resolution was rejected by an enormous majority. The Automobile Association is to be congratulated on its successful work for motorists during the last twenty-one years, and probably Mr. Brown will avail himself of its good offices if ever he gets into a motoring difficulty.

#### **CORRECTIONS.**

IN Dr. Horatio Matthews's letter on ophthalmic examination in infancy (July 17th, p. 136) for "presbyopia" read "hypermetropia."

**MR. A. P. BERTWISTLE** desires to call attention to two "inaccuracies" in the review of *A Descriptive Atlas of Visceral Radiograms* published in the **JOURNAL** of July 17th (p. 118). "Firstly," he says, "Dr. Rowden, senior, has been mistaken for junior; the former supplied about 120 [?] radiograms] against the latter's eight." The second "inaccuracy" seems to be that sufficient prominence was not given to the name of Dr. Spriggs, who supplied ninety excellent abdominal radiograms. Mr. Bertwistle says that "Dr. Rowden, senior, and Dr. Spriggs provided the backbone of the book."

#### **VACANCIES.**

**NOTIFICATIONS** of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 37, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 33 and 39. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 72.

## A SEARCH FOR AN IDEAL ANTIGEN FOR THERAPEUTIC IMMUNIZATION.

BY

SIR THOMAS BARDER, Br., M.D.,  
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL,

AND

N. S. FERRY, Ph.B., M.D.,  
PARKE DAVIS RESEARCH LABORATORIES.

It is now more than twenty years since Wright introduced the principle of therapeutic immunization against various microbic infections by the injection of bacterial vaccines. Wright's discovery gave an enormous impetus to the study of active immunity in microbic diseases. Although at first the range of therapeutic trial of the method of specific inoculation was of necessity much wider than it is to-day, experience has demonstrated that the principle has a much greater value in some infections than in others, and in certain types of disease than in others. It is probable that we do not even yet know the limits of the method, though it is already certain that it has limits, and these of a very definite kind. Especially is its value limited when infections are generalized and when the tissue resistance of the patient is at a low level. In the treatment of such a grave and common disease as acute streptococcal septicaemia, for example, the failure of vaccine therapy is notorious, while in chronic streptococcal endocarditis response to therapeutic inoculation does not occur.

It cannot be said that in specific antisera, at least in the case of the streptococcus again, the practitioner has a remedy which is much more potent than it was twenty years ago. There are those who consider that Besredka made an appreciable advance when he introduced the use of "sensitized vaccines," and certainly this mixed type of bacterial antigen, in combination with specific antibody, appears to be of definite value in the treatment of septicaemic processes when the infection is one for which a homologous antiserum is available.

In spite of the last-mentioned contribution to the subject, however, it cannot be said that the treatment of bacterial infections of the "pyogenic" class has advanced materially during the past decade, and this is true whether we consider the matter from the aspect of bacteriotherapy or of chemotherapy. Sometimes hope swings over to the side of chemical agents, at other times it turns to "specific" measures. Occasionally, since these things have a vogue at present, the physician wonders if physical processes may not possibly hold some more potent means available for the septicaemic patient. In the search for remedies the donor of blood has not been omitted, and various forms of "immuno-transfusion" have been exploited, though so far to very little purpose.

### NON-SPECIFIC INOCULATION.

Of late years a great deal of non-specific treatment of infective processes has been carried out by methods which are generically termed "protein shock." The undoubted benefits which have occasionally followed these efforts, the not infrequent improvement following directly upon the use of a bacterial vaccine which later experience of the case proves not to be specifically related to the infection, together with some other pieces of evidence, have led some observers to consider if most of the good results following the employment of bacterial vaccines may not be of the nature of protein shock. This doubt may, however, be read to be as much a measure of disappointment at the meagre results of vaccine therapy as a convincing conception of the mode of its action. For it may well be the fact that it is not so much that bacterial vaccines are not specific as that they are not specific enough. It can scarcely be doubted, in view of all the known facts of natural and of acquired immunity, that in the stimulation of the patient to produce specific antibody there lies, dormant but available, a much larger field of response than has hitherto been entered by the use of any antigen yet placed in the practitioner's hands.

It seems clear that a new method is essential in order to advance from the present position where the treatment of pyogenic infections has paused for so long. Wright's introduction of vaccine therapy gave a great fillip, not only to the treatment of infective processes by specific inoculation, but to the study of antigen therapy in general. It is important to cast about for new remedies of the antigen class, to devise new experiments with this object in view, and especially to maintain an open mind as to possibilities which may have become hidden, as possibilities oftentimes are hidden, by assumptions which have gone before and which, through the course of years, are mistaken for facts.

In this paper it is proposed to give a survey of the various forms of antigen that have been used for the purpose of therapeutic immunization and to describe a new one, with the steps which led up to its discovery and the uses to which it may, in our judgement, be put.

### SURVEY OF METHODS OF PREPARING ANTIGENS.

The methods of preparing bacterial antigens for immunizing purposes, proposed from time to time, have been many and diverse. Following the original discovery that suspensions of dead bacteria in a neutral medium, sterilized either by heat or by chemical action, were capable of protecting against bacterial infection, bacterial "vaccines" (Wright) have been used for this purpose almost to the exclusion of other forms of antigen; moreover, these bacterial vaccines have been considered to be a standard by which the immunizing values of other antigens could be measured.

Since the time when vaccines were placed upon a practical basis, however, a good many other antigens have been proposed, and have been actually prepared for purposes of laboratory research. A few of these have also been made available for therapeutic use. None so far has approached very nearly to the ideal antigen, perhaps little closer than did the original bacterial suspensions. The ideal antigen for therapeutic purposes should exist in aqueous solution; it should be protein-free; it should be non-toxic; it should be rich in immunizing properties.

The various methods adopted to prepare antigens for immunizing purposes may be reduced to four, according as the product of the method is (1) a bacterial suspension of a culture grown upon solid media, (2) the whole broth culture of a micro-organism, (3) the filtrate of a broth culture, or (4) an extract of the bacterial cells obtained in various ways. In all of these resultant products the antigen exists in a crude state, adulterated more or less with substances which are not only of no value in the process of immunization, but are not seldom extremely injurious to the patient, as well as to the antigen itself.

Although the exact nature of the antigenic substance is not known, since it has never been obtained in a pure state, it is undoubtedly specific in any particular antigen. In other words, each micro-organism has its homologous antigenic or stimulating substance, and the production of immunity depends upon some sort of favourable interaction between this substance and the cells and tissue fluids of the body. A weak antigen tends to excite the formation of a weak antibody, while a strong antigen stimulates an antibody response more or less proportionate.

In preparing antigens, therefore, whether for experimental or for therapeutic purposes, including the production of antisera, it has been the ultimate aim of all investigators to obtain these substances in a form which might stimulate the highest degree of specific antibody response with the least noticeable reaction on the part of the host. It has long been recognized clinically that severe general reactions, and to a less extent also severe local reactions, tend, in greater or less degree, to lower the resistance, or to diminish the defensive power of the body. This results from the failure of the tissues to respond to their fullest capacity to the stimulation of the antigenic substance, part of their energies being spent in combating substances not in the least concerned with the production of immunity, but harmful to the whole economy. Such relative failure is well illustrated in the attempt to produce immunity to diphtheria by the use of the broth filtrate of a culture of the diphtheria bacillus. This filtrate, which is in effect a solution of the diphtheria toxin, contains

both a poisonous portion, which is non-antigenic (non-immunizing), and an immunizing portion, which is non-toxic. In order to utilize the latter portion of the diphtheria toxin to its fullest extent in practice, the toxic portion is neutralized by the addition of diphtheria antitoxin, giving us the product known as the toxin-antitoxin mixture of Von Behring<sup>1</sup>; or it is rendered harmless by exposure to heat or to certain chemicals, leaving the toxoid or immunizing portion available as an antigen, the diphtheria toxoid of Glenny and Hopkins,<sup>2</sup> or the anatoxin of Ramon.<sup>3</sup> With the same object in view Larson,<sup>4</sup> by the use of soap, also produced a detoxicated diphtheria toxin.

Substances, such as various proteins, innocuous in themselves but prone to be poisonous when injected or absorbed parenterally, are invariably found in association with the antigenic substance in all antigens at present available. Such proteins—originating either from the bacterial bodies or from the media in which the bacteria have been cultivated—always excepting those which are intimately connected with the antigenic substance itself—are considered non-essential to the antigen and more or less harmful. To isolate the antigen proper from these proteins in a pure state has been a problem beset with many difficulties, since all known procedures for ridding the antigen of them have been undertaken only at the expense of weakening the value of the antigenic substance itself.

Seeing that the antigenic substance has been considered to be itself protein in nature, or to be closely associated with the proteins of the bacterial cell, it has been the practice of some workers to prepare extracts of the bacterial elements which should contain as much of the bacterial protein as possible, rather than to utilize the whole bacterial body as a form of antigen. In many instances, and where a special purpose was in mind, this procedure has proved fairly satisfactory.

One of the first and most widely used methods of extraction on these lines was that of Besredka,<sup>5</sup> who triturated in a mortar a mixture of salt and bacteria dried *in vacuo*. The extraction was carried out by the gradual addition, during trituration, of distilled water until the final content of salt in the solution approached 0.85 per cent. Macfadyen<sup>7</sup> and others have obtained important results by triturating frozen bacteria by special machinery and extracting with water or with salt solution. Another method turns upon allowing the bacteria to remain in their nutrient fluid media for prolonged periods. This method has disadvantages, in that it not only results in extraction of the proteins from the bacterial cells, but it permits of the retention, in the final product, of the autolysates and poisonous metabolic substances contributed to the media. This method, which was originally employed by Kraus<sup>6</sup> in the production of his antigen for the precipitin test, is used also in the preparation of some of the tuberculins. Prolonged incubation of a suspension, in normal saline, of live or of dead bacteria, will also produce an extract containing antigenic properties, but the antigenic value of a solution obtained in this manner is weak, and therefore it is of little value. It has been customary for many years to dissolve the bacterial cells in alkaline fluids, such as N/10 sodium hydrate, and from this solution to precipitate the protein. One of the best alkaline solvents for all except acid-fast bacteria was found to be "antiformin." It has been shown by several investigators that by the tryptic digestion of bacteria, as originally suggested by Hirschfelder,<sup>8</sup> antigen more or less free from extraneous constituents may be obtained.

While these various methods of extracting the proteins or so-called endotoxins from bacterial cells have been successfully applied when the antigen was merely required for certain serological purposes, it was early discovered that antigen obtained in these ways did not fill the role required of it from the clinical standpoint as a substitute for the whole bacterial cells themselves, and therefore other means of attaining the desired end have been sought.

D. Thomson in 1919<sup>9</sup> described an extract of the gonococcus and other micro-organisms prepared by dissolving the elements in N/10 alkaline solution and precipitating in a weak acid solution. The precipitate, washed and redissolved, resulted in an extract said to be non-toxic in nature and of high antigenic value. Extracts prepared in

this manner have been called "detoxicated vaccines." In 1920 Douglas and Fleming,<sup>10</sup> with a view to rendering bacterial cells more soluble in the body fluids and thereby more readily absorbed for purposes of immunization, extracted the elements with acetone by means of a Soxhlet's apparatus. It was found that the resulting material, in the form of a sterile, dry, white powder, was very soluble in media containing tryptic and other proteolytic ferments. These authors concluded that this type of antigen appeared to possess immunizing properties fully as great as those of vaccines, and also that it formed a very suitable antigen for use in complement fixation tests. Jenkins,<sup>11</sup> in 1921, by modifying the preparation of "detoxicated vaccines" as described by Thomson, and incorporating a method of detoxication described by Dean,<sup>12</sup> produced what he termed "residual vaccines." Dean had previously used hydrogen peroxide as a detoxicating agent in the preparation of various vaccines, especially of dysentery bacillus vaccine, and claimed that they were rendered non-toxic thereby. In 1923 Dreyer<sup>13</sup> gave us "defatted vaccines," later called "diaplyto" vaccines and antigens, and claimed that it was possible to obtain better results with the use of antigens freed from surrounding fatty or lipoidal material than with those prepared in any other way. While this work of Dreyer, as also that of Douglas and Fleming before him, appeared to lead to conclusions diametrically opposed to those following the researches of others, especially of Warden,<sup>14</sup> who held that bacterial antigen is lipid in character, it is interesting in that it would, on the surface, seem to prove that the specific antigenic substance may be obtained from different parts of the bacterial cell and by different methods.

#### THE NATURE OF THE ANTIGENIC SUBSTANCE.

During the past two or three years several investigators, and especially Heidelberger,<sup>15</sup> Zinsser,<sup>16</sup> Perlzwig,<sup>17</sup> and their associates, have been carrying out some extensive experiments in an attempt to throw more light on the character of the antigenic substance, and considerable progress has been made. Most of this work has been done with the pneumococcus, and certainly suggests that the possibilities of obtaining a protein-free antigen are by no means hopeless. In the course of these researches a soluble and highly specific substance was purified and concentrated from the three types of the pneumococcus by Dochez, Avery, Heidelberger, and others. This was obtained free from nitrogen, and appeared to be of a polysaccharid nature. This substance, however, is non-antigenic, while the protein substance is antigenic. Perlzwig, Steffen, and others isolated an antigen from the three types of the pneumococcus by prolonged tryptic digestion and extraction of the digest with 70 to 90 per cent. alcohol. This antigen is insoluble both in absolute alcohol and in ether, and in all lipoidal solvents. It is not impaired by boiling for five minutes nor by heating at 56° C. for one hour. It would appear from these researches that bacterial antigenic substance is, in the case of the pneumococcus at any rate, of the nature of a lipid, and that it probably adheres to the protein fraction of the cell in loose union.

#### A NEW TYPE OF ANTIGEN.

The work now to be summarized was begun in 1921 by Ferry and was continued by Ferry and Fisher. Many details of these researches have been already published.<sup>18, 19</sup> The experiments had for their purpose the determination of the practical value, from an immunizing standpoint, of bacterial antigens prepared after various methods. They were originally undertaken as the direct result of suggestions made by Horder. In carrying out the work a large number of antigens prepared from several different micro-organisms were tested, in the hope that a substance would be found fulfilling more satisfactorily than any in present use the requirements of an ideal antigen.

The work was first undertaken with broth cultures of the typhoid bacillus, colon bacillus, pneumococcus, and other bacteria of the (so-called) endotoxin-producing class. It was found that the antigenic properties of the filtrate were higher than anticipated, having regard to previous conceptions of the antigenic properties of broth filtrates

generally in this class of bacteria. It was also found that these properties varied more or less inversely with the time of incubation of the cultures. In other words, the shorter the incubation time, within certain limits, the higher the antigenic titre of the filtrate, the optimum incubation time being from eighteen to twenty-four hours. Filtrates from cultures incubated for five and ten days were very low in antigenic power. This experiment was carried out several times with similar results, leading to certain deductions which were contrary to ideas previously held. Reasoning from past experience with diphtheria and tetanus toxins and with toxins of similar nature to these, it was concluded, in the first place, that the antigenic substance pertaining to the class of bacteria under observation is probably not of the extracellular type, because if it were it would probably have been stronger at the end of several days than at the end of eighteen or twenty-four hours. It was concluded, in the second place, that if the antigenic substance were of the endotoxic variety, strictly so called, it would again have been found stronger after several days' incubation than after the early stages, since more of the antigenic substance would have been dissolved out of the cells and have been evident in the filtrate. It would seem, therefore, that this stimulating substance which we term antigenic substance must be more or less loosely bound up with the bacterial cell and is to be found in the broth as a washing from the bacterial surface or ectoplasm rather than as an extract from the endoplasm of the cell.

As a result of these observations with broth filtrates it was argued that, if the antigenic substance could be so easily washed off the bacterial cells and was to be found in the broth as early as eighteen hours after planting, it ought to be obtained, and in a higher degree of purity, in the washings of bacteria grown on solid media. In order to prove this point some preliminary tests were carried out with the typhoid bacillus. This micro-organism was chosen because it grows very readily on ordinary media and because the antigenic properties of the particular strain of typhoid bacillus in use were more or less known to us. In carrying out these experiments twenty-four-hour agar growths were washed off with normal saline and the suspensions of bacilli were immediately agitated for a few minutes in a mechanical shaker more quickly to yield a homogeneous suspension and to facilitate the extraction of the antigenic substance. In order to clarify the suspension of bacilli with as little loss of antigenic properties as possible, it was passed through a Sharples centrifuge in place of a porcelain filter, for it had been found earlier in the work that if the washings were passed through porcelain filters they lost, probably by absorption, more or less of their antigenic power: for this reason clarification by means of the centrifuge was here adopted. These washings, when received from the centrifuge, proved, as anticipated, to be highly antigenic, even more highly than the broth filtrates, and in some instances more highly than the suspensions of bacilli from which the washings were obtained. The washed bacilli were, in every instance, very low in antigenic content, showing that the mere washing had taken from them a large part of their immunizing power.

In carrying out the experiments with the broth cultures and the cultures grown on solid media all operations were done as quantitatively as possible. Twenty-four hour broth cultures or salt suspensions of the bacilli, grown for the same length of time on the solid media, were divided into three parts: one part or fraction to be tested as a whole; one part to be centrifuged for the preparation of the filtrate fraction, which we called the "centrifugate"; and one fraction to be centrifugized for the sediment. This last fraction was diluted to the original volume with normal salt solution. These fractions were sterilized by the addition of 0.3 per cent. cresol instead of heat, as experience had shown that heat is injurious to antigen, especially to the immunizing portion of it. The antigenic or immunizing properties of these fractions were determined by injecting them intravenously into rabbits of equal weight in the same number of doses, usually four, and testing their serums, according to various serological methods, for antibody content.

Washings from other bacteria also supposed to be of the endotoxic variety, such as the colon bacillus, pertussis bacillus, streptococcus, gonococcus, and especially the pneumococcus,<sup>20</sup> were prepared and tested as above, and antigens of extremely high value were obtained. These results corroborated the work on the typhoid bacillus, and confirmed the deduction that the antigens of this type of micro-organism are very loosely bound to the bacteria, and that it is not necessary to break up the bacterial cell in order to liberate the antigenic material.

The fact that the bacterial cells were intact and, so far as the eye could discern, were not broken up, was shown by means of staining and observing under the microscope, and also by plating, a comparison being made between the number of colonies obtained and the number of bacteria in the original suspension.

#### "ECTOANTIGEN."

A very important point was brought out at this time—to wit, the fact that washing the organisms in this way extracted the antigenic substance from the bacteria, while the toxic principles were left behind. Tests showed that the washings were non-toxic, while the washed bacterial cells were practically as toxic as before, as they produced reactions similar to the unwashed cells. The toxins or poisonous substances retained in the bacterial cells, therefore, are apparently endotoxic in nature, while the antigens are seemingly derived in great part from the ectoplasm. The antigens in question, therefore, are in all probability not identical with the endotoxins or endopoisins, as has been taught, but appear to be entirely different substances. As it would appear from these results, and others which Ferry and Fisher have reported, that the antigenic or immunizing portion of the bacterial cell is more ectoplasmic than endoplasmic in origin, it is proposed to call this type of antigen an "ectoantigen," and for products prepared in such a manner as to contain only this ectoantigen the designation "immunogens" is suggested, to distinguish them from other antigenic products already in use.

A further study of this type of antigen elicited several other facts of extreme interest. One of the first experiments in the attempt to produce an antigen of superior value was carried out by treating broth cultures with sodium hydroxide, as this chemical had been used for a number of years by many investigators for the disintegration of bacteria, in the belief that by destroying the bacteria the endotoxin or antigenic substance is set free. The results, however, were disappointing in that the antigenic properties were found to be more active in the original broth cultures and in the broth filtrates from the original culture than in the material remaining after the sodium hydroxide had been allowed to act. There was no doubt about the fact that the bacteria were broken up and the contents set free, but the liberation of the so-called endotoxin in no way increased the antigenic properties of the filtrates. On the other hand, something, probably the alkali, had a very injurious effect upon the antigen, since the broth culture and its filtrate stimulated rabbits to produce agglutinins of the titre of 1 in 16,000 and 1 in 10,000 respectively, while the fractions acted upon by the alkali only stimulated agglutinins of titres as low as 1 in 150 and 1 in 2,000. Somewhat similar experiments were next carried out, using antiformin instead of sodium hydroxide, and the results were practically the same. The immunizing value of the antigen was nearly destroyed during the process of extraction.

#### TITRES OF BACTERIAL WASHINGS.

Another experiment was undertaken to show the relative values of bacterial autolysates, artificial aggressins, and bacterial washings ("immunogens"), as it was felt by some that these three products must be closely related. The results, however, were very convincing of the fact that they were not at all alike. Serum resulting from the injection of the agar washings gave an agglutination titre of 1 in 12,000 and a complement fixation titre of 1 in 750, while the aggressins gave titres of 1 in 5,000 and 1 in 500 respectively. The autolysate from the residue of the agar washings gave titres of 1 in 3,000 and 1 in 100, while that

from the residue of the broth filtrate titred 1 in 5,000 and 1 in 500. An autolysate from an agar culture not previously manipulated in any way gave an agglutination titre of 1 in 7,000. We have concluded from these results that autolysates and agglutinins are antigenic, not because of the lysis of the bacteria or of the extraction of the antigen by shaking and long standing, but because they contained some of the antigen which had been washed from the exterior of the bacterial cell and which had lost some of its antigenic properties as a result of the method of treatment. The more of the antigen that is previously washed off the cell, the lower will be the titre of the serum stimulated by the sediment left by lysis or the autolysate from the sediment, whether washed or unwashed.

Nitrogen determinations of these bacterial washings show that the total nitrogen in them is very much lower than in that of any other bacterial antigens at present in use, including such well known antigens as bacterial vaccines, glycerinated vaccines, detoxicated vaccines, and serobacterins. The fact that the washings were low in nitrogen content and high in antigenic properties led to experiments to determine, if possible, if washings rendered protein-free would show any immunizing properties. Three methods of precipitating the protein were followed, including the use of acetone, phospho-tungstic acid, and uranium acetate. In the first method the acetone was removed by evaporation under vacuum in order to use as little heat as possible, and in the third method the solution was freed from uranium by precipitation with sodium phosphate. Agar washings of *B. typhosus*, *B. coli*, pneumococcus, streptococcus, and gonococcus apparently protein-free were found to stimulate antibodies of appreciable value, as shown by agglutination and complement fixation tests.

As a final experimental procedure tests were carried out on animals in order to compare these washings with therapeutic antigens prepared after various other methods. The results in every instance were favourable to the washings. In carrying out these tests rabbits were given three intravenous injections each of the antigens, diluted to contain the same number of micro-organisms per cubic centimetre, or their equivalent in antigen, and bleedings were made seven days after the last injection. The serums from these rabbits were then tested for antibody content, according to several well known serological methods, and the results tabulated. As stated above, the antigenic properties of the washings per cubic centimetre, estimated on a quantitative basis, exceeded those of any of the other antigens tested.

It was concluded, therefore, as a result of these last tests and others previously carried out, that these washings more nearly approached the ideal antigen than any which had come under the observation of the writers. This last statement is based on the fact that these washings are in aqueous solution, are low in protein content, are high in antigenic properties, and are practically non-toxic.

#### CLINICAL RESULTS AND DOSAGE.

Following the experimental work on these "immunogens" steps were next taken to test them on a practical basis. They were sent to a considerable number of clinicians, choosing those who had suitable cases in their clinics, and who were known to be conversant with, and able to give time and attention to, systemic observations of their patients throughout the treatment. While the first trials were carried out more or less as a preliminary measure in order to determine the safety of the remedies, the results justified the procedure, and a more extensive trial was then attempted. The subcutaneous, intravenous, and intramuscular routes for injection of the antigen were compared. So also were various intervals of time in the course of different disease processes. Altogether these trials have been pursued over a period of two years. The intramuscular route appears to be the one of election, and daily injections appear to give the best results. These conclusions are, however, only tentative, since the experience of different observers varies, and the best mode and the interval of injection doubtless depend upon the type of the disease, whether acute or chronic, general or local.

It has been found by a series of trials that the most useful concentration of the antigen is one which allows of

an initial dose of 0.5 c.cm., with increments rising to 2 c.cm., and, on occasion, to 5 c.cm.

It is as yet too early to speak of the main results of the use of this antigen, still less of statistical results. To quote concrete cases, however successful they appear to have been, can avail little, although it is hoped to do this later when a larger number have been collected. Already, it may be said, however, this form of antigen has become the favourite one in the hands of a good many practitioners who have had experience of various types of these remedies. Promising reports are forthcoming in connexion with streptococcal, pneumococcal, and gonococcal infections especially. That reactions of an undesirable kind are absent after injection of this antigen is a fact recorded by almost all those who have used it, and this clinical observation confirms the results of its experimental use in the laboratory.

## SYMPTOMS, PATHOGENY, DIAGNOSIS, AND TREATMENT OF ADDISONIAN ANAEMIA.\*

BY

A. T. TODD, M.B., M.R.C.P.,

ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY; DEMONSTRATOR  
OF PATHOLOGY, UNIVERSITY OF BRISTOL.

This disease is worthy of consideration on account of its frequency—I have been meeting with one case a month for the last two years—and because of the mistaken diagnoses which have been made: neurasthenia, neuritis, chronic rheumatism, pelvic pressure neuritis, food poisoning, colitis, and carcinoma of the liver have been some of the diagnoses in this series—tragic mistakes, for the disease appears to be amenable to treatment if only the diagnosis is made early.

#### SYMPTOMS.

Symptoms are often few and vague, and in a series the presenting symptom shows much variability; tiredness or weakness and the symptoms of anaemia are the most common. Dyspepsia is often met with, but pain is usually slight and vomiting rare. Diarrhoea alternating with periods of constipation is a symptom of importance, and is found in about 50 per cent.; it precedes the anaemia by years, and, as the patient has always had it, information about it is not volunteered. It is severe at times and diagnosed as colitis; in one case a severe attack following a meal of suspected fish led me to diagnose food poisoning for two weeks. Premature greyness occurs in a large number of the cases. Glossitis, another symptom which precedes the anaemia, is common; painful cracks and fissures occur for years, and each patch heals slowly, leaving behind it atrophied epithelium devoid of papillae. These atrophic patches spread gradually over a large part of the tongue, and produce the smooth glazed tongue of the declared condition. This glossitis appears to be the sequel of suppurative periodontitis, past or present, and it is found apart from the disease under discussion, though rarely to the same degree. In the less marked cases the glossitis may be unmasked by swabbing the tongue over with dilute acetic acid.

Nervous symptoms, usually those of subacute combined degeneration, are frequent in the later stages of the disease, but symptoms of this condition were the presenting complaints in a third of the series. Abnormal sensations, due to degeneration of the sensory tracts or nerves, are the first and are very misleading, for there is no loss except of deep sensation; the vibration sense, fortunately one of the easiest to test, is one of the first to disappear. As the sensory changes are modified qualitatively, rather than

\* A paper read before the Bath and Bristol Branch of the British Medical Association.

quantitatively, a diagnosis of neurasthenia is given. The motor tracts are affected later; the pyramidal tract is, as a rule, the first to suffer; the spastic paresis resulting augments the fatigue of the anaemia. A flaccid paresis usually follows, but Babinski's sign persists. Symptoms due to intoxication of the higher levels are not infrequent, but, apart from those due to the relative anoxaemia, they occur at a much later stage, and are of no value for diagnosis; acute confusion, depression, and Korsakow's psychosis are frequent. Nervous changes in the upper extremity are less prominent, but of the same kind as in the legs; they occur later. A rapid ascension of the nervous symptoms is occasionally seen; in Case W. it was interesting, although humiliating, to follow the extension to abdomen, thorax, and arms. Trophic changes are late, and, as a rule, terminal.

#### COURSE.

The disease is of long duration, and has been present for years before it is diagnosed. As will be shown later, it may be termed a congenital disease in most cases. It consists of gradually lengthening waves of anaemia separated by gradually shortening remissions of relatively good health, apart from diarrhoea and glossitis. Hunter says it is the third wave which is diagnosed, but there are probably many ripples, and the waves are difficult to map out. These early waves readily respond to treatment, but recovery occurs without treatment, unless the resistance of the patient is so slight that the condition becomes aplastic at the outset. The later waves are progressively less amenable to treatment, and the aim of this paper is to encourage earlier recognition of the disease.

#### ETIOLOGY.

This is obscure still. A few cases follow intoxication with known substances—thorium, radium, and  $\alpha$  rays; some aniline and arsenical derivatives, and toxins of roundworms and tapeworms. These act by depressing the bone marrow, and cause an anaemia which is indistinguishable from the primary one.

Experimentally an anaemia very nearly related to Addison's type can be produced by injecting known haemolytic substances.<sup>1</sup> Seyderhelm<sup>2</sup> produced an anaemia of this type in dogs by making a stenosis of the ileum; he found that anaemia developed only when the gut above the stenosis became infected with faecal organisms. This experiment was planned to reproduce the condition found present in cases of Addison's anaemia; it has been known for some time, from operation and post-mortem experience, that there is a faecal condition of the contents of the small intestine in these cases, and an atrophic gastro-enteritis similar to the atrophic glossitis already noted.

This infection of the upper alimentary tract would appear to be due to the gastric achlorhydria found in all but a few cases of this disease—the Guy's Hospital school say that it is invariably present; I shall return to this point. The gastric hydrochloric acid is a strong antiseptic—an acidity of pH 4.0 will kill many strains of *B. coli* and streptococci; acidities much stronger than this are found in the normal stomach; I have found acidities of pH 1.0. Culture of normal gastric and upper small intestinal contents shows that most of the bacteria visible are dead, but from these viscera in Addison's anaemia rich cultures of streptococci and other organisms are obtained. It is thought that this failure of normal antiseptics and the absence of a related antiseptic power of the succus duodenalis<sup>3</sup> lead to a progressive infection of the alimentary tract with absorption of toxic substances which cause the

anaemia. The cases of anaemia of this type occurring after gastrectasis support this contention.

The cause of the achlorhydria is not yet determined; it is often ascribed to the purulent periodontitis present in practically every case, or previously existing. It is thought that the continuous swallowing of pus leads to gastritis and diminution of acid secretion, just as frequent ingestion of alcohol is known to do. The effect of pyorrhoea on the gastric secretion deserves more study; it is often stated that pyorrhoea leads to hyperacidity, or acid retention, but in several advanced cases I have found complete achlorhydria; this may, however, have been congenital. It has been found that 4 per cent. of normal persons have complete achlorhydria, but Addison's anaemia does not attain this frequency.

Many single organisms have been blamed for the disease: streptococci, spirochaetes, *B. coli*, monilia, and, of late, *B. welchii*. The occurrence of the last-named organism in excess is probably dependent upon the absence of antiseptics. Most importance is attached to streptococci in England and to *B. coli* on the Continent. The toxins of both cause anaemia in animals, and *B. coli* is known to produce a neurotoxin which may well be the cause of the nervous changes so frequently present. Though the common strains of *B. coli* are not capable of producing haemolysins, they do produce haemolytic substances from certain amino-acids which may occur in the small intestine.<sup>4</sup> Moreover, truly haemolytic strains of *B. coli* would appear to be more frequently found in this disease than is at present generally believed; in five out of six cases

haemolytic strains were isolated at the first attempt; experiments with these organisms are proceeding, and one throws some light on the etiology.

Two rabbits were used and two others kept as controls. Both pairs were put on a vitamin-deficient diet with casein and as much alkali added as the animals would tolerate; this was done to diminish gastric acidity, to supply amino-acids, and to allow bacterial proliferation. The controls were not treated in any other way, but the experimental animals received living cultures of *B. coli* and streptococci isolated from cases of anaemia with nervous changes. Both groups showed anaemia, but the controls rather less. The corpuscles of the controls diminished in size, but the corpuscles of the experimental pair showed an increase (Chart 1). One of the experimental rabbits developed spastic paralysis of the hind legs and was killed; the spinal cord showed patchy degeneration of the white matter, a condition very similar to that found in Addison's anaemia in man. It may be that this change was due to the avitaminosis, but no similar change has been found in the controls, which had exactly the same diet. In addition, the liver of this rabbit showed a free iron reaction, and before death the urobilin in the urine was increased to one hundred times the normal.

The belief that the soil is of as great importance as the seed deserves some notice, especially as several very different seeds are known to be causal. If we replace this gardening simile by another, we have one which satisfies the known facts better: we should liken the patient to a loaded gun—several things may pull the trigger. Harst<sup>5</sup> has collected from the literature and his practice 49 cases of familial occurrence of this disease. In one of the early cases of my series there was a strong family history—the patient's mother and grandfather had died of the disease. Having diagnosed Addison's anaemia in this patient (W.) I advised that the relatives should be examined; I found that both her children were anaemic, and that one had complete achlorhydria, and also that one of the patient's sisters was in the early stages of the disease. Since then I have examined the relatives of every case possible, and show the results of eight families in Table I. In the family B.1 the father of the patient died of the disease, and both his children show complete achlorhydria. In case C.1 a brother is

CHART 1.

| Daughter of D. ...    | 26   | 7.4                     | 5-10       | 16               | 5.7              | 120          |

\* Suspiciously high values.

suffering from anaemia of long duration, but I have not been able to obtain any further details. Other local familial occurrences are reported to me by Dr. Harvey and Dr. G. Hadfield. A glance at Table I shows that achlorhydria or hypochlorhydria is frequent, and that either anaemia or an excess of red blood corpuscles and haemoglobin is very common. This excess rather points to the presence of some toxic action on the bone marrow with excessive blood formation. Thus hypochlorhydria or achlorhydria and instability of blood formation are very frequent in predisposed subjects, and it is contended that similar conditions are probably present in all cases—that is, that the soil is of importance.

We must leave the etiology, concluding that the toxins or toxic decomposition products of organisms normally saprophytic produce depression of haematopoiesis in a predisposed individual. These toxic substances may act in several different ways: (1) Simple depression of the marrow with the production of badly formed red cells which are rapidly removed from the circulation by the reticulo-endothelial system. (2) The toxic substances stimulate the reticulo-endothelial system to excessive haemolysis, and the marrow is exhausted secondarily. (3) The toxic substances depress the inhibition of the adrenal gland on the reticulo-endothelial system.<sup>9 11</sup>

We must leave the question at this point, for the evidence does not warrant a definite answer.

#### CLINICAL SIGNS.

It is rather unfortunate that the disease is called an anaemia, for, apart from the waves of haemolysis, there is little if any anaemia. In the intervals the blood values are normal or above normal. Thus Case W. was investigated by many consultants and two senior pathologists, and was reported free from any sign of anaemia, yet she was very anaemic when I saw her first, and died within three months.

As is well known, during the anaemic periods there is a high colour index, polychromia, and the presence of nucleated red cells, megaloblasts especially being significant. The high colour index requires explanation; in the remissions it is about normal. It appears to be due to the fact, first stressed by Price-Jones,<sup>6 10</sup> that the average size of the red cells is increased in Addison's anaemia—it is a megalocytic as well as a haemolytic anaemia. This does not mean merely that megalocytes are present, for they are

found in any anaemia; it is the average size, which is greater than normal.

Normally the red cells vary between 5 and 9  $\mu$ , the average being given as 7.5  $\mu$ . Price-Jones finds it to be 7.3  $\mu$ ; my own value and that of some others<sup>7</sup> is 7.4  $\mu$ . Normal values I find to range between 6.9 and 7.6  $\mu$ . Table II shows the averages in as wide a collection of blood diseases as I could find, and it will be seen that the values are all below 7.7  $\mu$ ; in Table III the values in Addison's anaemia are given, and the lowest is 7.7  $\mu$ . In no other disease have such high values been found with the exception of emphysema<sup>10</sup> and malaria, in a case of which I have found a value of 7.8  $\mu$ , probably due to the abundance of parasites present. This increase of size is the one constant symptom; it remains during remissions and allows a diagnosis to be made when there is no anaemia. Also, these large cells can contain more haemoglobin, for in the anaemic waves the marrow appears to be able to turn out haemoglobin more easily than corpuscles.

It is probable that this increased diameter of the red cells is not always present, although the exceptions must be very few; two cases of subacute combined degeneration have been described recently which had normal values<sup>1</sup>; in two of my cases the values, though above the normal, were low for Addison's anaemia, and one of these cases was exceptional in showing some gastric hydrochloric acid.

To support a diagnosis of Addison's anaemia we expect to find (1) anaemia, (2) leucopenia, (3) absence of wasting, (4) increase of the average size of red cells, (5) glossitis or its sequelae, (6) achlorhydria, and (7) evidence of excessive haemolysis—that is, excessive urobilinuria and increase of indirect bilirubin in the blood. To every one of these there are exceptions: (1) has already been noted; (2) waves of leucocytosis are not infrequent; (3) wasting is common in the later stages, and when not obvious is often masked by a slight anasarca; (4) exceptions have been noted already,

if we are to conclude, in agreement with the Guy's Hospital school, that subacute combined degeneration occurring in anaemia is confined to the Addisonian type—a conclusion not generally accepted; (5) glossitis may be little marked; (6) in a series of 51 cases Faber and Gram<sup>6</sup> found 4 in which some free hydrochloric acid was present; my Case M. also shows free hydrochloric acid; these appear to be the only cases which have been fully examined; it has been objected that the cases of Faber and Gram were bothrioccephalus anaemia; this cause was not found, although these observers were alive to the possibility; in my case there is no evidence and little likelihood of worm infection; (7) evidence of excessive haemolysis is not found in the remissions and in the cases becoming aplastic (note Chart 2 of Case W.—the urobilin and bilirubin diminish to normal values in spite of increasing anaemia).

Measurement of the red cells may be made in several ways; the best, I think, is actual measurement with a carefully calibrated ocular micrometer. A green monochromatic screen is of help. Three to five hundred cells, taken as they come, are measured and an average made, or a curve, as recommended by Price-Jones,<sup>8</sup> is compared with the normal. Where there is considerable increase a glance is sufficient to give a diagnosis, but in the lower values fully 500 cells should be measured. Such a count takes me about ninety minutes. American observers find that 200 cells are sufficient, and that the count can be made in twenty minutes.<sup>7</sup> There are several ways other than this. A very pretty one, when the staining turns out well, is to make the suspect film on the top of a film from a diabetic patient with acidosis; the corpuscles of the latter take a basic dye, while the suspect's cells take an acid stain.<sup>13</sup> In the lower values this method is of no value.

The cause of this megalocytosis is not the achlorhydia, for a glance at Table II will show that in several cases with achlorhydia normal values are found; in bothrioccephalus anaemia, where there may be no achlorhydia, the values are above the normal.<sup>6</sup> The experiments of others<sup>1</sup> and my own show that this permanent increase is to be ascribed to the presence of toxic substances acting on the marrow; a temporary increase occurs in some forms of acidosis.<sup>12</sup>

## APLASTIC ANAEMIA.

This is most commonly regarded as a separate disease, although usually discussed with Addison's anaemia. The diagnosis is not made frequently, and is apt to be considered a guess. The features of this anaemia are said to be: severe anaemia; presence of a haemorrhagic tendency due to thrombopenia; absence of evidence of blood regeneration, marked leucopenia and scarcity of nucleated red cells; smallness in size of the red corpuscles; absence of marked or any excess of haemolysis; presence of a gelatinous marrow in the long bones; generally fatal issue, the few survivors probably being cases of purpura haemorrhagica, which simulates, and may even terminate in, aplastic anaemia.

Four cases in my series have acquired these features after showing all the signs of florid Addisonian anaemia. In Case W., shown in Chart 2, the red cells diminished in size and number and at the same time urobilin and bilirubin fell to normal values. The explanation is that the marrow is turning out so few corpuscles that there is not enough material for excessive haemolysis. In Case E. (see Table III) the low diameter coincided with a severe wave of anaemia; the following higher value accompanied a remission. In Cases C.1 and C.2 a diminishing value is seen; these cases could not be worked out so completely as Case W.

CHART 2.—Note that urobilin index is the product of percentage and amount in ounces.

From these observations, confirmed by *post-mortem* examination in Case C.2, it is inferred that aplastic anaemia is merely a terminal phase of Addison's type, and that this variety would be more frequent if the patients survived longer. It may, however, be the first manifestation of this or any other anaemia where there has been a heavy intoxication of the marrow or where the haematopoietic power is low at the outset. It is important to recognize the transition, for treatment is disappointing in this stage; blood transfusion leads to transient amelioration only; in two of the cases it gave me the impression that it accelerated death.

Before considering treatment the part played by the endocrine glands requires mention. Evidence of disease is often found *post mortem*, and this would be expected. Thyroid changes are common<sup>9</sup>; Case Y. requires 3 to 5 grains, and Case D. has been receiving 15 grains of thyroid extract daily; the possible influence of the adrenal gland has been noted. It will be of interest if both the diseases named after Addison are found to be associated with lesions of the same gland. The condition of the pancreas is of greater practical importance, for evidence of defect in its external secretion is found with some frequency, and this would have been regarded as inevitable until recently; the external secretion of the pancreas was said to be stimulated by secretin produced by the inter-

action of hydrochloric acid and the duodenal mucosa. According to this theory the digestion of proteins was almost impossible in achlorhydria, for peptic and tryptic digestion could not occur. We now know that hydrochloric acid is not indispensable, but the atrophic condition of the duodenal mucosa raises the suspicion that it is deficient of pro-secrelin. Examination of the stools shows that in many of these cases flesh is poorly, if at all, digested; yet, in view of the anaemia, the patients are urged to eat as much of it as possible; the result is putrefaction and the production of further toxins to depress the marrow.

#### TREATMENT.

There are many treatments, and the effect of any one is difficult to gauge when the nature of the disease is remembered; no matter what treatment is given, the marrow will respond as long as it can, and a remission will follow. At the present stage of our knowledge the indications are:

1. Stimulation of the blood-forming activity of the marrow.
2. Improvement of gastric and intestinal digestion.
3. Diminution of intestinal infection.

#### Stimulation of Haematopoiesis.

Septic foci around the teeth, accessory sinuses, or wherever found, should be removed. The removal of tissue causing haemolysis—that is, splenectomy—used to be practised with some frequency, and is still advised. It is not performed so frequently as it was, and should only be considered where there is splenomegaly. The series of Giffin and Szlapka<sup>14</sup> is regarded as the chief authority, and these authors base their conclusions on survival. A review of the operation in other places gives a high mortality, and shows that the remissions were not often of long duration; survival is very variable with any treatment; my Case Y. has survived eleven years, although for about eight of them he had no treatment. Another operative method in use at present is the removal of marrow from the long bones, with the hope that a new marrow will regenerate; it is usually preceded by blood transfusion, and remissions occur.

More direct methods are the exhibition of arsenic, which remains our sheet anchor; it may be given in any form, and the form does not appear to be very important. In certain schools in Germany it is given in enormous doses. If there is actively spreading nervous disease arsenic must be carefully watched, for it is a nerve poison. Iron does not appear to be of any value, but it is hoped that its use intravenously may cause a blockade of the reticulo-endothelial system and give the same result as splenectomy, without its danger; experiments on this line are being made. Cholesterolin, with the object of providing stroma for the red cells, has been recommended; I have not had any success with it.

Blood transfusion, an excellent stimulus for the bone marrow, is widely practised, and if the marrow is still capable of response it acts well. In the cases showing signs of aplasticity it does little, and may well be conceived to do harm; when the marrow is almost exhausted the provision of donor's blood may remove any stimulus to regenerate, and the struggle is given up. It has been noted that in two such cases transfusion gave the impression that death was hastened. When blood transfusion is given it is advised to group the donor and recipient and give blood of the same group; if the blood count of the patient is under one million grouping is difficult, and a Group IV donor should be chosen. The results of transfusion are well known, and many, some even permanent, remissions follow; it should be pointed out that at the menopause an anaemia occurs associated with some excess of haemolysis, and in about 50 per cent. with achlorhydria; these cases do well on iron and arsenic, but transfusion gives a permanent remission. With earlier recognition of Addison's anaemia transfusion will be seldom required.

#### Improvement of Digestion.

This is largely accomplished by the provision of the missing hydrochloric acid. This must be given in large

doses, commencing with 45 minims and increasing as rapidly as possible to at least 2 drachms. The dose must be modified to the diet; this latter dose after a meal like afternoon tea will give pain. The 2 drachms of acid are given in 7 to 10 ounces of water flavoured with sugar and lemon juice; this is sipped towards the end of, and shortly after, each meal. It must be taken for the rest of the patient's life. This amount of acid has been found to bring the acidity of the stomach to the normal, and should permit peptic digestion, and it is hoped that it will stimulate pancreatic secretion. Where there is active dyspepsia this should be preceded by a short course of bismuth and hydrocyanic acid until gastric irritability is less marked. If, as is common, pancreatic digestion is defective, flesh should be sparingly ordered at first; the diet should be mainly lacto-vegetarian. In several of these cases I have tried pancreatic extract, but have not found any certain benefit.

#### Intestinal Antisepsis.

In addition to the help afforded by the procedures noted in the section above there are some more direct methods. Koumiss, lactic cultures, or *B. acidophilus* cultures all have the same action and are interchangeable; they act, like the lacto-vegetarian diet, by increasing the acidity of the intestinal contents, and so reduce the growth of streptococci and *B. coli*. As a lacto-vegetarian diet is monotonous and sometimes repugnant, this method of giving cultures with an ordinary diet will afford a welcome interlude. Given with a mainly carbohydrate diet they are of more value still.

Kaolin, from its power of adsorbing toxic substances and precipitating micro-organisms, is indicated. It is given either dry or suspended in water the first thing in the morning; my patients readily increase to three heaped teaspoonfuls.

Colonic lavage through an artificial anus appears to be giving good results, and is a rational treatment where the urinary indican remains high in spite of the measures so far outlined.

Vaccine therapy (streptococci and *B. coli*) is still on trial; it is too early to be sure of its value.

Treatment of the nervous symptoms is the same as that of the anaemia. When the anaemia has disappeared the only treatment is re-education, but this gives very good, although slow, results.

#### CONCLUSIONS.

1. Addison's anaemia is a common disease, and through most of its course is not an anaemia.
2. Diagnosis is possible in the pre-anaemic stage.
3. In the early stages treatment is highly successful, but must be perpetual.
4. In the later stages exhaustion of the marrow, or aplasticity, supervenes, when treatment is without result.
5. Hereditary transmission of the anaemia, and of relative or complete achlorhydria, is so frequent that the relations of any case should be examined for these defects.

I am indebted to Dr. J. A. Nixon and Dr. G. Hadfield for a few of these cases. The expenses of this research have been met by a grant from the Colston Research Fund. I am indebted to Professor I. Walker Hall for advice and stimulation.

# A NOTE ON THE CARDIAC SYMPTOMS OF PERNICIOUS ANAEMIA:

WITH PARTICULAR REFERENCE TO CARDIAC PAIN.\*

BY

CAREY F. COOMBS, M.D., F.R.C.P. LOND.,

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, BRISTOL GENERAL HOSPITAL.

THE following observations are based on notes of thirty-six consecutive sufferers from pernicious anaemia. In one of them, an elderly man, the picture was perhaps rather that of an aplastic anaemia; yet there was enough reason for looking on it as a haemolysis to which his bone marrow could not respond, to justify its inclusion in these notes. My present purpose is to call attention to two facts that have some clinical significance. The first of these, the simulation of cardiac disease by pernicious anaemia in its early stages, was forcibly impressed on my mind by an experience that I shall briefly relate.

About two years ago I was spending a week-end in the country; and, having need of a telephone, went in search of one at the village post office. It was a warm Sunday afternoon, and when I attacked the private house adjoining the post office, some time passed before my knocking brought out a stout, middle-aged woman, who was so scant of breath and so inclined to cyanosis that even on a June Sunday afternoon in Somersetshire I could not help speculating on the state of her myocardium. A few weeks later I was called to this same village by the doctor in whose practice it lay, to see a patient who proved—to my great interest—to be the lady of the post office. I was told that for some months she had been short of breath, and losing weight rather quickly; also that she had been troubled by polyuria. Her pallor was remarked on, but it made no great impression on me—partly, perhaps, because the room was darkened by a very heavy thunderstorm. Her pulse was 98 to the minute and regular; the blood pressure was 150 mm. Hg systolic and 70 diastolic; she seemed a trifle cyanosed. The heart was not obviously enlarged, and indeed the only local sign of disease was a loudish systolic murmur heard all over the front of the heart, but especially at the apex. Apart from a few rales at the bases nothing abnormal was found. She was in bed, and we decided to keep her there, with a provisional diagnosis of myocardial degeneration of senile type.

As the course of events proved, it was a severe anaemia that had depreciated the value of the cardiac muscle; and though its subsequent behaviour has not been exactly that of a pernicious anaemia the moral is the same: I ought to have examined the blood.

This is, however, not an isolated experience. In ten of my thirty-six cases the first diagnosis made was that of heart disease. Six of these patients were elderly, and their symptoms were of the kind that arise from the myocardial changes common at such ages: dyspnoea, oedema, and cardiac pain. In two, men of about 40, the rapid bounding pulse and basic murmurs had given rise to a suspicion of aortic valvular disease. In one other, to be alluded to later, there was in fact aortic disease as well as pernicious anaemia. Last of all, a woman of 40 was at first thought to be suffering from chronic ulcerative endocarditis, and indeed it may yet prove that she has this disease as well as the haemolytic anaemia that has been shown to exist.

My second point is this: that among the symptoms of myocardial disease sometimes exhibited by the patient with pernicious anaemia cardiac pain has a place; 8 of my 36 patients complained of it. In 2, attacks of substernal pain during exertion constituted the first evidence of ill health. In another patient, a woman of 56, two terribly severe attacks of precordial pain with collapse were observed during the last weeks of life, the second one being almost immediately fatal. There was no autopsy. A fourth complained of a heavy pain over the chest and shoulders, a fifth of a painful sense of constriction round the waist, and a sixth of a tearing, pressing pain in the centre of the chest and both arms; in all these it was brought on by exertion. Another, a woman of 63, had a brief attack of mid-sternal pain while we were examining her. It made her groan and lean forward with an anxious look. The case of the eighth patient, a man of 56, differed from the rest in that he had, from the first, quite definite physical signs of aortic disease in addition to the characteristic symptoms of pernicious anaemia. *Post mortem* this view of his case was confirmed; he had a diffuse atheroma of the aorta.

It is possible that all my other examples of cardiac pain in pernicious anaemia are also to be referred to a coincident cardio-sclerosis. All the patients were of an age to which such an explanation might be applied, yet none of them showed any signs of cardiac disease, apart from this one man; and Reid's<sup>1</sup> recent inquiry into the heart of pernicious anaemia discovered a noteworthy absence of cardio-sclerotic changes. Moreover, Dr. Todd has shown me some electro-cardiograms which suggest that there are certain changes in the curve which are peculiar to severe anaemia. Finally, the incidence of cardiac pain in cardio-sclerosis with pernicious anaemia is higher than in cardio-sclerosis alone.

At all events, let me be content to record the fact to which I have only once seen any allusion elsewhere, in a paper by Herrick and Nuzum<sup>2</sup> written in 1918—that patients with pernicious anaemia sometimes experience cardiac pain.

## DISCUSSION ON

## FOOD DEFICIENCY CONDITIONS IN RELATION TO PREVENTABLE ILLNESS.

## OPENING PAPERS.

I.—STUART J. COWELL, M.B., B.Chir. Cantab.,  
M.R.C.P. LOND.,  
Sheffield.

## THE SCIENTIFIC POINT OF VIEW.

THE past few years have witnessed an enormously increased interest in dietetic problems. Stimulated by the researches of scientific workers during the early part of this century into the nature of the foodstuffs necessary to maintain animals in health, and the consequent discovery of vitamins, men and women all over the world have been tackling problems of health and disease in man in the light of this new knowledge. The public at large has to a certain extent become acquainted with the more dramatic results of our dietetic investigations, and there is a real danger of its being led astray by the half-truths that are being served out to it by the lay press and by commercial advertisers. In these circumstances it is our duty to ascertain as far as we can the real facts concerning food deficiency in so far as they affect our own people, so that whatever practical measures we advocate for dealing with the situation may have the greatest chance of success. It is quite likely that a great deal more preventable illness results from defective diets than we recognize at present. Animal experiments and clinical observation have, however, yielded positive evidence of the relationship between dietetic deficiencies and certain common diseases met with in this country. I propose in this opening paper to limit myself to the discussion of these common diseases and the methods that may be used for their prevention.

We are not, of course, concerned here with food deficiency in the sense of diminution in the total quantity or energy value of a diet, nor do we intend to discuss at length the effect of alterations in the relative amounts of protein, fat, and carbohydrate contained in any particular diet. We know that the proportions of these food constituents can be varied very considerably in an adult's diet without producing signs of ill health. Moreover, some of us are beginning to realize that even the delicate alimentary canal and tissues of the infant need not be regarded as hypersensitive to slight alterations in the composition of

\* Given before the Bath and Bristol Branch of the British Medical Association.

its food in respect of these three constituents, provided the diet is adequate in certain other qualitative respects, which we shall refer to later.

In general, the food deficiency conditions which we to-day recognize to be responsible for preventable illness are related to deficiencies of vitamins. Recent work has made it clear that the amounts of the vitamins necessary to maintain an animal in good health vary considerably in different circumstances. Mellanby<sup>1</sup> has taught us that many factors in a diet, and particularly the amount and quality of the cereals it contains, may determine the minimum amount of fat-soluble vitamin necessary to prevent or cure rickets. Similarly Plimmer<sup>2</sup> has described the variations in the amount of vitamin B necessary to maintain young birds in health, according as the amounts of protein, fat, and carbohydrate and the total energy value are varied in the diet. Therefore, the mere presence of the essential vitamins in any diet is not necessarily sufficient to ensure maintenance of health, but there must be a balancing of the quantity of vitamin with other factors. We may cite the following specific instances of this balancing mechanism. Mellanby<sup>1</sup> has shown that when oatmeal or the germ of cereals is given to puppies severe rickets will develop unless a very considerable amount of the calcifying vitamin is added to the diet. Again, butter contains a moderate amount of this vitamin, but rickets can be produced in dogs receiving quite large amounts of butter if the diet contains oatmeal; the addition of extra calcium to the diet containing oatmeal and butter will prevent the occurrence of rickets. Furthermore, it has been established that exposure of an animal or of its food to ultra-violet rays may compensate to a very considerable extent for the absence of the antirachitic vitamin D from a diet. The decision concerning the presence or absence of vitamin deficiency is, therefore, not always easy, and can only be arrived at by consideration of numerous factors connected with the individual's diet and environment. In these circumstances it is not strange that the various practical suggestions that may be offered by responsible advisers to alleviate food deficiency conditions may differ considerably and yet all rest on some sort of scientific basis. This may be illustrated by a review of our present ideas concerning the etiology and means of prevention of rickets.

Rickets is one of the common food deficiency diseases met with in this country. This statement will even to-day probably not pass unchallenged. On the one hand, there are still men holding responsible positions in the medical world who regard the application to clinical problems of our knowledge of vitamins obtained from animal experiments as a "stunt," and refuse now, as they always have refused, to accept any etiological connexion between rickets and specific food factors. On the other hand, the recent striking discovery of the effect of exposing the skin or the food of an animal to ultra-violet rays, as regards the promotion of bone calcification, has caused many medical men to regard rickets as a disease produced primarily by fog and smoky atmosphere. No one who has had the opportunity of observing closely the experimental and clinical work on which Mellanby's views concerning the etiology of rickets are based can fail to recognize that dietetic factors are of supreme importance in the control of this disease. On the basis of this work the following are some of the conditions which we might expect to lead to the occurrence of rickets in children: (1) the deficiency of the antirachitic vitamin in an otherwise well balanced diet—as, for example, in an infant being breast-fed by a mother whose stores of the vitamin are below normal; (2) the absence of a sufficient supply of calcium in a diet which contains only a small amount of antirachitic vitamin, as in a child who is receiving little or no milk; (3) the presence in a diet of excess of cereal, and especially oatmeal, without a corresponding increase in the antirachitic vitamin to balance it; (4) the absence of solar irradiation combined with a relative deficiency of vitamin D, as in children brought up on poor diets in smoky industrial areas, particularly in winter time. If these factors are the chief ones operative among our children in producing rickets, the prevention of the disease ought to be relatively simple: we should either take steps to ensure that the

child, from the moment of its birth, was supplied with a sufficiency of antirachitic vitamin, or we might see that the child was regularly exposed to natural or artificial sunlight.

Before proceeding to discuss the principles involved in providing an adequate supply of vitamin for the child, I propose to deal in a general way with the respective merits of ultra-violet irradiation and the supply of fat-soluble vitamin. This is a subject of practical interest at the present time. Large sums of public money are being asked for, and in some cases obtained, for the setting up of artificial sunlight clinics in our industrial cities for the purpose of preventing and treating rickets and malnutrition. Before public funds are applied on any large scale for this purpose we ought to be reasonably certain that the result will justify the expense. In the first place it must be recognized that irradiation, either of the skin or of the food, will compensate only for deficiency of the antirachitic vitamin in the diet. Normal growth and maintenance in health of a young animal deprived of vitamin A, the distribution of which is very similar to that of vitamin D, is impossible for any considerable length of time, whether the animal is irradiated or not. In illustration of this principle we may note the observations of Bloch,<sup>3</sup> who has reported cases of xerophthalmia in children due to deficiency of vitamin A, which have not responded to weeks of ultra-violet irradiation, but which have quickly cleared up under the influence of vitamin A supplied in the form of cod-liver oil. Therefore it would still be important to ensure an adequate supply of fat-soluble vitamin in a child's diet even if he were regularly receiving exposures to ultra-violet light. Next, what evidence have we as to the relative effectiveness of the two methods purely from the point of view of preventing or curing rickets? As far as experimental work on animals goes, it would appear that the giving of fat-soluble vitamin is more efficacious than the irradiation of either the skin or the food of an animal. Both methods may be successful when the diet is only moderately deficient, but when animals are given really bad diets including abundance of the rickets-producing cereals (oatmeal or germ), cod-liver oil is found to have a more potent antirachitic effect than irradiation. From the clinical point of view it must be allowed that the irradiation of children can in most cases cure active rickets. Precisely the same statement applies to the giving of cod-liver oil, although there are still members of the profession who do not believe that the oil has any specific action in this respect. Cod-liver oil has been prescribed to children for many generations past as a cure for all sorts of conditions, so that mothers are apt not to be impressed with it as a specific remedy. As the oil is frequently disliked by the children, unless prescribed in infinitesimal quantities mixed with malt, it frequently happens that the mothers do not trouble to give it regularly and in adequate quantities; consequently the doctor who has ordered it, or who is told that it has already been given, often gets the impression that it has no great antirachitic effect. Irradiation has therefore the advantage of being a spectacular proceeding which will appeal to the average mother more strongly than the homely remedy of cod-liver oil, and will be pursued with more or less enthusiasm.

Occasionally cases of rickets are met with which do not respond either to ultra-violet irradiation or to cod-liver oil. For instance, I have met with a case of renal rickets in which there was no increase in the calcification of the bones after two months of treatment by means of cod-liver oil, natural and artificial sunlight, and irradiated milk. Cases are also reported in which cod-liver oil given by the mouth has proved ineffective. But the desired result has been obtained by the subcutaneous injection of the oil or of a concentrated preparation of it. Such instances are, however, rare and do not affect our main conclusions.

We have seen that the giving of cod-liver oil has the advantage over irradiation of providing for an adequate supply of the growth-promoting vitamin A as well as the calcifying vitamin D. What evidence is there that irradiation has beneficial effects which cod-liver oil does not have? In this connexion I propose to turn for a moment from the subject of rickets to that of infantile malnutrition.

Malnutrition, or marasmus, in infants is not generally recognized as a food deficiency condition, but very many of the cases could with some justification be included in this category on account of the remarkable way in which they respond to the addition to their diet of fat-soluble vitamin. In Sheffield, where I have had the opportunity of observing most of the marasmic infants admitted to the Royal Infirmary during the past three years, the vast majority of these babies quite rapidly improve in their general condition and put on weight when given the diets suggested by Mellanby,<sup>4</sup> the principle of which is the addition of adequate supplies of the vitamins to feeds of cow's milk, diluted if necessary. In some infant welfare centres, I believe, marasmic children are being treated with "artificial sunlight" and good results are apparently being obtained. Is there any evidence that the light produces effects in these cases which fat-soluble vitamin does not? On theoretical grounds we might expect that the light effect would be inferior to the vitamin one, as light can by itself induce merely temporary growth, apparently by mobilizing reserves of vitamin A stored in the young tissues. Be this as it may, cases of marasmus are occasionally met with which respond promptly to ultra-violet rays after the condition has been more or less stationary for many weeks in spite of an adequate supply of fat-soluble vitamin. In two or three cases I have seen wasted infants with this kind of history who have started to gain weight at once when their milk was exposed to ultra-violet rays before being given to them. The explanation of such results is not clear, and I do not propose to discuss it here. The point I wish to emphasize is that such cases are rare, and the vast majority of infants can be successfully reared even in our smoky cities without the aid of artificial sunlight, provided they are supplied with adequate quantities of fat-soluble vitamin; irradiation may prove of value in the rare cases of malnutrition that do not respond to dietetic treatment alone.

To revert now to the subject of rickets: we have seen that this disease may be regarded primarily as a food deficiency disease, and should therefore by definition be preventable by dietetic measures alone. We may now inquire what principles should guide us in dealing in a practical way with the problem of its prevention. First and foremost it is of the utmost importance that the child should be born with ample reserves of fat-soluble vitamin in his tissues, and therefore preventive measures should begin with the pregnant mother. The influence that the feeding of the pregnant mother may have on the health of her child is only now beginning to be appreciated from the standpoint of physiology. It is a subject of such great importance that it is worth while considering it in some detail. Animal experiments have demonstrated conclusively that relatively large amounts of both vitamin A and vitamin D can be stored up in the tissues of the young provided the mother obtains a liberal supply of them in her diet.

In most of the experimental work now carried out in connexion with the growth-promoting vitamin A, young rats are employed. Workers used frequently to be puzzled by anomalous results that appeared in different litters that were receiving experimental diets. The animals from one litter would continue to grow for long periods after they had been receiving diets deficient in vitamin A, while the growth of animals from another litter which were receiving exactly the same diet ceased rapidly. The explanation is now known to be that one mother had been getting in her diet but a moderate amount of the vitamin, while the other had been getting a liberal supply. The same principle applies in the case of the antirachitic vitamin D.

Mellanby<sup>4</sup> has demonstrated the effect of pre-natal feeding on the development of rickets in puppies. To give an example of these experiments, he kept two bitches who were pregnant by the same father, and fed one on a diet containing abundance of fat-soluble vitamin and the other on a diet that was deficient in this respect. After they were weaned the puppies from the two litters were reared in pairs, a puppy from the well fed mother receiving the same diet as a puppy from the badly fed mother. When this diet was moderately deficient in

respect of its fat-soluble vitamin content it was found that the puppy whose mother had been receiving the poor diet developed severe rickets, while the puppy whose mother had been well fed had almost normally calcified bones. Furthermore, it was demonstrated that the influence of the mother's diet lasted for a considerable period in the life of the young animal. One puppy from each mother in the above experiment was given an adequate supply of fat-soluble vitamin, and at the end of four and a half months they both had normally calcified bones. Their diet was now changed to one deficient in fat-soluble vitamin. Six months later the animals were almost fully grown, but the one whose mother had been badly fed had developed severe rickets, corresponding to late rickets met with in children, while the other, whose mother had been well fed, still had normally calcified bones.

Similar results have been reported by Grant and Goettsch,<sup>6</sup> working on the subject of rickets affecting rats. They found that the diet of the mother was a very important factor in increasing or diminishing the resistance of the young to rickets when there was a deficiency of antirachitic vitamin in their diets. In fact, they make the statement that among rats "under ordinary circumstances rickets does not develop in the young of well nourished mothers when a lack of the antirachitic vitamin is the only deficiency in their diet."

In the experiments just quoted the mothers usually received their experimental diets during both pregnancy and lactation. That the diet during each of these periods is of great importance for ensuring reserves of vitamin in the young is further indicated (a) by the fact that the fat-soluble vitamin content of eggs varies greatly with the fat-soluble content of the diet of the hen, and (b) by the fact that the fat-soluble vitamin content of milk has been shown, both in the case of cows and nursing women, to vary according to the fat-soluble vitamin content of their diet. Obviously, then, the feeding both of the pregnant and of the lactating mother is a most important determining factor in the development of rickets and malnutrition in her offspring, and if means were taken to ensure that during pregnancy and lactation all mothers received a well balanced diet containing ample supplies of fat-soluble vitamin it is probable that infantile rickets would become a rare disease and the incidence of malnutrition would be very materially lessened.

In the case of infants who for any reason cannot be fed on the breast, and in the case of all children during the first few years of life, the prevention of rickets can be practically ensured by giving them an adequate supply of cod-liver oil. Even infants during the first few weeks of life tolerate the oil in almost all cases. After they are weaned the children should receive a well balanced diet which should include milk, as this is the only considerable source of calcium in common foodstuffs, and foods which are comparatively rich in fat-soluble vitamin—butter or beef dripping (in preference to margarine or "bacon dip"), eggs, and cod-liver oil.

If these simple dietetic measures resulted in the virtual elimination of rickets and the diminution of the number of cases of malnutrition it would seem well worth while on these grounds alone to make strenuous efforts to put them into effect. But we have evidence that these same measures would result in further important beneficial effects. I do not wish to enter into any lengthy discussion of Mrs. Mellanby's work concerning the relationship between food deficiency and dental defects, but the subject is such an important one that it cannot be neglected. Mrs. Mellanby has demonstrated that fat-soluble vitamin exerts a profound influence on the structure of the teeth. The teeth of a young animal can be made to develop well or ill by varying the amount of antirachitic vitamin and other factors in the diet, precisely as can the bones of the animal. The feeding of the pregnant and lactating mother has been shown similarly to influence enormously the structure of the teeth of the young. Mrs. Mellanby has not confined her observations to experimental animals, and has studied the relationship between the structure of the teeth in children and the incidence of dental caries. She finds that, in general, badly formed teeth are far more liable to caries than well formed teeth, and has demon-

strated that the development of dental caries in children can be markedly influenced by dietetic means. We are justified in drawing the conclusion that if children were brought up under the dietetic conditions which are most likely to ensure the prevention of rickets, their teeth would be better formed and much less liable to decay.

Lastly, there is considerable evidence that deficiency of fat-soluble vitamin has a potent influence in predisposing animals, and especially young animals, to infections, particularly of the respiratory and alimentary tracts. Whether this influence is due to the lack of vitamin A or of vitamin D or of both has not been definitely settled. That vitamin D is concerned in raising the resistance of tissues to infection is suggested by the increased bactericidal power of the blood induced, as shown by Colebrook, Eidnow, and Hill,<sup>7</sup> by exposure of the skin to ultra-violet rays, the action of which in other directions is similar to that of vitamin D. Whatever the mechanism may be, there seems to be little doubt about the fact. For instance, infantile diarrhoea is less liable to occur when an adequate supply of fat-soluble vitamin is given. This has been frequently observed in the case of experimental animals, and that it is true in the case of children would appear highly probable from the pronounced effects on the incidence of this condition that have apparently resulted from the routine administration of cod-liver oil to babies in institutions such as homes for illegitimate children. The occurrence of respiratory diseases in children would seem similarly to be affected by the supply of fat-soluble vitamin. Mellanby<sup>5</sup> has pointed out that pneumonia is practically never found in puppies that have been brought up on good diets including cod-liver oil, whereas it is quite common in puppies receiving deficient diets. It is common knowledge that rickety children are peculiarly liable to catarrhs, bronchitis, and bronchopneumonia. It is therefore highly probable that if mothers received during pregnancy and lactation ample supplies of fat-soluble vitamin, their children would be to a very large extent protected from these disorders during the early months of their life.

To sum up: it would appear possible at the present moment practically to eliminate rickets, to improve enormously the condition of the teeth of our people, to lessen the infant mortality from malnutrition, diarrhoea, and respiratory infections, and in general to raise the standard of physique and health. The measures that are recommended to bring about this result are quite simple. Ensure an adequate supply of fat-soluble vitamin in the diet: begin with the pregnant and lactating mother and continue with the child from the earliest days of his independent existence. When the child is weaned, the less milk, eggs, and butter that can be included in his dietary, and the less opportunity he has for being exposed to natural ultra-violet rays, the more important is it that he should be given cod-liver oil or one of its reliable preparations, and that foodstuffs such as oatmeal, which have a rickets-producing effect, should be excluded from his diet.

 Physician to the Queen's Hospital for Children, Hackney.

## THE CLINICAL POINT OF VIEW.

THE clinician is confronted with a totally different problem with regard to food deficiency diseases from that of the laboratory worker. The laboratory worker gives a diet deficient in certain respects and watches the results of the basic diet given alone or with certain additions. The clinician is confronted with the results, and must attempt to elucidate the tangled causes, whether dietetic, hygienic, or infective, and he is constantly faced with the fact that a given symptom may result from any one of a great variety of causes. However, it is obvious that in order to deal successfully with dietetic diseases he must know

what deficiencies are likely to arise. Since these vary greatly in different parts of the world, the following remarks must be taken to apply solely to conditions in this country.

In the hope of getting the views of others, I will put forward the statement that, excluding clinical rarities, specific food deficiencies definitely known to cause illness in this country are few in number—the chief being deficiencies of iron, organic antirachitic factor, antiscorbutic vitamin, and probably iodine in certain districts. Other deficiency diseases may be present among the population, but their presence is as yet unproven.

Examples of the latter are diseases due to insufficient vitamin B, a deficiency of which brings about, among other results, intestinal atony and consequent stasis; but I would suggest that there is as yet no sufficient reason for assuming that chronic constipation and digestive disturbances are frequently due to deficiency of this vitamin, or that an increased supply would cure these cases or materially lessen their incidence. Vitamin B has a wide distribution. It is found in meat, eggs, milk, potatoes, tubers, roots, green vegetables, peas, beans, nuts, and fruit, and is not easily destroyed either by keeping or by heat, so that the presumption—until disproved—would be that it is present in sufficient quantity in any mixed diet. Unlike some recent writers, I would expect that if there existed a slight but widespread deficiency of this vitamin occasional sporadic cases of beri-beri would occur, but this disease is almost unknown in Great Britain. Similarly, keratomalacia, associated with deficiency of vitamin A, and pellagra, probably associated with a deficiency of certain amino-acids, with or without other dietetic defects, are extremely rare.

Far be it from me to say that, apart from clinical rarities, the only food deficiency diseases occurring in this country are those due to deficient iron, vitamin C, vitamin D, and iodine. It may be that there are many others, but if they commonly occur I, for one, do not find myself able to diagnose them when I meet them, and I believe most other clinicians are in the same position. If anyone will refute me, and contribute evidence of their occurrence and discuss their differential diagnosis, the information would be most valuable.

My own work is almost confined to children, and I will therefore, only attempt to consider some aspects of the preventable disease in children caused by deficiencies of iron, vitamin D, and vitamin C, to all of which children are more susceptible than adults. I hope some other speaker may deal with iodine deficiency.

Iron, with a protein and a pigment—namely, globin and haematin—is necessary for the formation of haemoglobin. Biochemists tell us that the proteins and pigments of the diet are probably adequate under any ordinary conditions to supply the globin and haematin of the body, but there is much evidence as regards young children that the necessary supply of iron is often lacking, and that the so-called alimentary anaemia of infants is due to a deficiency of iron in the diet, and not to any form of milk or fat toxæmia, as has been suggested. We know that the iron content of milk, both human and cow's milk, is low, and insufficient by itself to supply the needs of the growing infant, so that the child is largely dependent, until such time as it receives a mixed diet, upon the iron store present in the liver at birth. If this store is exhausted before the child gets food richer in iron than milk and cereal it must become anaemic. Most of this iron store is laid down in the later months of pregnancy, so that the premature infant, born with a small iron deposit, invariably becomes anaemic, often profoundly so, before 5 to 6 months of age if not supplied with additional iron. This condition can be cured by giving iron as a drug by the mouth. After an interval of two to four weeks, sometimes longer, during which the haemoglobin percentage remains stationary, there is usually a steady rise week by week up to 70 per cent. or higher. Among full-term infants minor grades of anaemia are also extremely common. For example, of a group of 40 fairly healthy infants, aged 3 to 18 months, examined this spring at a welfare centre, 25 cases (60 per cent.) had less than 70 per cent. haemoglobin in the blood as estimated by Haldane's method.

he normal is probably something over 70 per cent. haemoglobin at this age. Of these 25 cases, one had only 45 per cent. haemoglobin and four more between 50 and 60 per cent., so that we may safely assume that anaemia is very common in infants, though we cannot assume that the whole of it is due to iron deficiency. Its prevention is one of the problems badly requiring investigation. I have attempted to give an emulsion containing iron as a prophylactic, but without success, as it was unpalatable and I was unable to persuade the mothers to continue giving it with any regularity when they considered their infants healthy. Points on which we require further information are: how much of this anaemia in full-term infants is due to deficiency of iron, and what are the simplest and most efficient means of prophylaxis in such cases.

Deficiency of the antirachitic factor or vitamin D is, so far as definite evidence goes, one of the commonest food deficiencies among children in this country, but the presence of widespread ill health in the adult community due to this cause has not been established.

I need not remind you that the antirachitic factor is formed in the skin, as well as in various foodstuffs, by the action of ultra-violet light, and that on this account the amount needed in the diet varies with the degree of exposure to light. During the summer it is uncommon in London to find a child showing evidence of inadequate antirachitic factor, or, in other words, suffering from active rickets, though of course cases do occur. The "fresh" cases of rickets develop for the most part between January and April—that is, after the darkest months of the year—and in spring it is still a very common disease in the East End of London. In a recent radiographic investigation of 167 unselected new out-patient cases aged 1 week to 2 years, carried out during April at the Queen's Hospital for Children, we found that 8 per cent. of cases had x-ray evidence of rickets, or, taking only cases aged 4 to 13 months, 15 per cent. of the series. Of course in northern manufacturing towns the incidence is much higher. It is, therefore, during the winter and early spring that special precautions should be taken to ensure adequate vitamin D in the diet, and undoubtedly cod-liver oil is the source of the vitamin on which we should chiefly depend. Infants getting 1 to 1½ pints of cow's milk—or, for that matter, of human milk—in the day have been found to develop rickets when leading an indoor life. Cream and butter, too, are found to have a variable, but low, antirachitic value when compared with cod-liver oil and other fish oils. In the spring of last year I found that a mixed diet containing meat and vegetables as well as milk had little or no curative effect on rachitic children living indoors, so that we may legitimately conclude that if a young child is kept indoors it will probably suffer from a deficiency of vitamin D unless special measures are taken to supply this vitamin. It seems a very great pity that when cod-liver oil is available enormous sums should be spent by the public under medical direction on widely advertised proprietary preparations which are relatively poor sources of this vitamin. A cod-liver oil emulsion, begun gradually and given three times a day in the bottle (say a total of 1 drachm of the oil in the day), is well tolerated by almost all infants.

As regards conditions of ill health, other than rickets, due in part to deficiency of this factor, I would mention tetany (the cause of convulsions in many infants between 6 and 24 months of age), and respiratory infections, which account for a great rise in the infantile mortality in the winter months. In our observations at the Vienna University Kinderklinik it was found that the amount of infection of the respiratory tracts (including spread to the middle ear with otorrhoea) was very much less in a group of infants having cod-liver oil than in a comparable group without.

I should like to repeat that if every artificially fed infant, and every breast-fed infant that was little out of doors, were given cod-liver oil throughout the winter, it seems probable that all but the slightest manifestations of rickets would be banished, and the incidence of colds, bronchitis, otorrhoea, and convulsions in infancy would be lessened, with a consequent lowering of the infantile mortality. Moreover, the amount of dental caries should also be

diminished, since deficient vitamin D is one among the many factors leading to decay of the teeth.

Turning next to the *antiscorbutic vitamin*. Infantile scurvy is not a common disease in London, and I do not think that so-called incipient scurvy occurs frequently either. It would be interesting to know the views of others in this connexion. There is one proprietary preparation, or rather two recommended to be used in sequence, which are probably responsible for more cases of scurvy than all other methods of feeding in this country put together. The second of these two is a dried milk with an addition of malted flour recommended by the makers for infants from 3 to 6 months of age. Possibly we may hear some views from the public health standpoint concerning how this danger can best be brought to the notice of mothers. So-called "sterilized milk" which is sold by dairies and is often two weeks old by the time it is consumed, and pasteurized milk also account for a certain number of cases of scurvy every year.

Orange juice is in very general use in London as a prophylactic, but when oranges are expensive tomato juice is an excellent substitute which needs popularizing among mothers instead of the less effective grape juice. The contrast between the incidence of infantile scurvy in London and in Vienna I found striking, and was probably due in part to the widespread use of orange juice in London.

Perhaps I might mention one other common deficiency—this time a drink deficiency. We must all have been struck on many occasions by the improvement seen in sick children as the result of giving liberal amounts of water—as much as they care to take—after a period of deficient intake. One sees this improvement most strikingly perhaps in two conditions, diarrhoea and high pyrexia, for instance, with pneumonia. Unfortunately many members of the public believe that water is harmful in such conditions, and so withhold it, to the distress and detriment of the child. The public also need instruction, I think, in the desirability of leaving water accessible to children at and between meals, so that they may take as much as they wish—there is no reason to suppose they will take too much.

To sum up. Of the three dietetic deficiencies in children which I have asked you to consider—those of vitamin D, vitamin C, and iron—the diseases associated with the first two are well recognized and we are already steadily diminishing their incidence; but the fall in their incidence, in my opinion, could be greatly accelerated by our consistently advocating the prophylactic use of cod-liver oil and of orange or tomato juice for all artificially fed infants and many breast-fed infants. These rich sources of vitamins D and C are within the reach of practically all sections of the community. The prophylaxis of alimentary anaemia is a much more difficult question. But iron deficiency is very widespread, at any rate during the first one to one and a half years of life, and the resultant ill health should be preventable. Much more information of a practical kind as to how this can best be achieved is urgently needed.

III.—SIR PERCY W. BASSETT-SMITH, F.R.C.P.,  
D.T.M. AND H.CAMB.,

Physician, Hospital for Diseases of the Chest, Victoria Park, E.

#### THE TROPICAL MEDICINE POINT OF VIEW.

It is often stated that the endemic population of tropical climates under natural conditions is free from dietary diseases so common in those living in temperate climates. This is only partially true, for in certain parts the struggle for existence is very severe and the food supply is so short—as, for instance, North-West Australia—that intestinal diseases from the consumption of unsatisfactory forms of food are very common. The same results are, I believe, found in parts of Africa, Borneo, etc., due to mutilation of the teeth. It is, however, certain that to maintain good health it is necessary for all races to supply and take the right kinds of food, and that this shall not be deprived of important factors by the methods of cooking often employed. No doubt exercise and sanitation are very necessary, but it is the food absorbed that supplies the energy and strength required to carry out the duties of our early life.

Within recent years our knowledge of the important

subject of dietetics has increased and widened, and a very large number of experiments, both human and animal, have been carried out. Quantities of books and pamphlets have been written on the subject; still the public often do not see these, and they are slow at grasping the vast importance of a right dietary for their daily life and well-being. It is a sad fact that much of what is good food is very largely deprived of one of the most important attributes by the modern processes of preparation and preservation. The habitual rush of the present century life has brought into existence the want of a large supply of food, quickly produced and rapidly obtainable in the most handy form, and also the poor appetite of the over-worked man demands greater variety and more highly spiced kinds.

It has been frequently shown that the old belief that so many calories of a mixed diet containing protein, fats, carbohydrates of starch and sugar, with salts and water, was sufficient for life, is not the whole truth. To ensure life, growth, and the maintenance of health the various so-called vitamins or accessory food factors are necessary; without these food consumed is but inert or dead for vitalizing the tissues of the body. This essential fact must be grasped first when making out any scale of dietary.

The following table shows a dietary for ordinary work in the tropics as described by Ghosh. Here the total value is much less, about 2,500 calories, with a minimum of fats, high carbohydrates, and good protein value.

*Dietary for Ordinary Work in the Tropics (Ghosh).*

|                                   | Grams. | Proteins. | Carbo-<br>hydrates. | Fats.   |
|-----------------------------------|--------|-----------|---------------------|---------|
| Bread ... ..                      | 224    | 17.92     | 112.0               | 8.36    |
| Meat ... ..                       | 168    | 44.8      | —                   | 25.2    |
| Cheese ... ..                     | 28     | 8.68      | —                   | 7.84    |
| Eggs ... ..                       | Two    | 2.8       | —                   | 6.44    |

Total number of calories: 3,087.

Sugar is a most valuable article of diet in the tropics, especially for men doing hard labour. I have been much struck by the descriptions of the great value placed on, and craving for, sugar by those climbing the mountains of the Andes in Peru. It is not only a heat producer but also a saver of proteins.

Tropical heat has thus, undoubtedly, a great determining action upon many physiological processes; for instance, under its influence the respirations are reduced in number, less oxygen is inspired, less carbon dioxide and water are given off by the lungs, and there is, therefore, a tendency to the retention of carbonic acid and alveolar air in people while at rest, also to the production, particularly in the rich, of glycosuria and acidosis. The urine is reduced in quantity from an average of 15,000 c.cm. to 5,000 to 7,000 c.cm. per diem. There is a reduction of chlorides and nitrogen excreted. The blood, as has been indicated, shows an increase of sugar content, and the Arneith count-index is said to be pushed to the left.

The digestive powers are less vigorous than in cold

climates, and large quantities of food cannot be well borne in the tropics. The food given should be such as to produce the minimum of heat, but giving sufficient nourishment. Proteins, in themselves, stimulate metabolism and also produce heat, and naturally are physiologically less required; if, however, much physical labour is taken the requirements of a greater supply of protein are evident. Woodruff states that "all natives in the tropics are in condition of partial nitrogen starvation, and need more nitrogen than they can get." To say that in the tropics we should live like the natives is quite wrong, as examples of certain enthusiastic, but misguided, missionaries could be quoted. He also states that the destructive effects of the concentrated actinic tropical rays on protoplasm cause the necessity of more nitrogen than at home (which is a debatable question), and he thinks that it untrue that fat is not needed in the tropics. It is evident that in arranging a dietary the conditions of work and the varying states of life must be taken into consideration.

There is no need for me here to describe the various forms of vitamins and their character, as this has already been done by other speakers. I give here a short synopsis of the tropical diseases due to deficiency in dietary:

1. Oriental beri-beri and infantile beri-beri.
2. Occidental beri-beri.
3. Ship beri-beri.
4. Rancid scurvy.
5. True scurvy.
6. Epidemic dropsy.
7. Pellagra.
8. Rickets.

In tropical climates the deficiency diseases mostly centre around the inadequate supply of vitamin B, hence it is the study of this factor which is the most important. The antineuritic factor was first found in the rice polishings, and subsequently in varying amounts in many other substances, and all three vitamins are often found in the same substance—milk, eggs, green vegetables, tomatoes and yeast. The vitamin B has been obtained in a concentrated condition from rice polishings as "ticque-ticque" from yeast—"marmite," a palatable preparation of yeast and other extracts; and vitamin C by condensing orange juice *in vacuo*, but all attempts to obtain a pure crystalline substance have so far failed. As constituents of our diet a great deal of attention has naturally been paid to the stability under conditions of cooking and storage of food stuffs. Vitamin B is unchanged for a long time in dry storage and is fairly stable in ordinary cooking operation. It would appear that it is as essential to the normal life of a plant as to the animal which derives its whole supply from the vegetable world, directly or indirectly, for evidence of the synthesis of a vitamin in the animal world is known. Confirmation of this is found in the fact that yeast and moulds require provision of the water-soluble vitamin B to start their growth; a small amount only is required and the plant will then continue to thrive by synthesizing its own supply.

According to Finlay, vitamin B is essential for the formation of nucleic acid in the body. For this reason muscular activity or any condition of growth, by rapidly using up vitamin B, shortens the incubative period of the subsequent polyneuritis. Drummond notices that a diet deficient in vitamin B produced sterility in male rats, which is in accordance with the views generally held of the relationship between vitamin B and nuclear metabolism.

The most important deficiency disease in the tropics is beri-beri, which is caused to a great extent by a lack of vitamin B in rice-eating natives, and has been traced by the careful and persistent investigations of Fraser, Stanton, and others in the Malay States, to the almost exclusive use of white polished rice as the staple article of diet—that is, rice which has been deprived of its outer layers and embryo in which the vitamin B is contained. By using coarse milled rice the disease could generally be prevented. It is not exactly known what it is that actually gives rise to the symptoms, but a large amount of clinical facts have been brought forward to substantiate the view of Fraser and Stanton. It is not only adults that suffer but there is an infantile form found in suckling infants of beri-beri mothers; this can be cured by giving extract

of rice polishings or by extracts of yeast. The same disease occurs in other countries where the staple diet is white bread or potato starch, and it was prevalent during the war among the troops in Mesopotamia, and in the Eastern levies in the South of France. The diet that produces beri-beri in the few can hardly fail to have a deep-seated and bad physiological effect on the many; ordinary everyday evidence of this is seen in native settlements in the East. When we consider the extent to which the European in the tropics has often to exist on canned foods and milk, and a relative absence of fresh green vegetables, it seems not unlikely that some at least of the evils ascribed to the climate may be really due to the food.

With regard to beri-beri, which is usually classed as a true deficiency disease, it must be pointed out that the Japanese still hold the view that the polyneuritis of birds, due to the ingestion of polished rice in which the deficiency of vitamin B is the cause, is different from true beri-beri. This view is supported by Megaw, in a recent paper, who places epidemic dropsy as a form of beri-beri, similar to ship beri-beri. His view is that in the present state of our knowledge it is unsafe to assume that a deficiency of vitamin B is the cause of beri-beri, but that it is a disease due to some change, probably bacterial, in the rice, which occurs on faulty storage—a toxin being formed which may be the essential cause of some forms of beri-beri and possibly of the disease in general. There is another theory, held by Vedder, that polyneuritis and dry beri-beri are chiefly due to a deficiency of vitamin B in the diet, and wet beri-beri and epidemic dropsy, and perhaps ship beri-beri, to a distinct and as yet unknown factor.

From a naval point of view, the beneficial action of eating "scurvy grass" was recognized by Captain Cook, but it was due to Dr. Lind and Sir Gilbert Blane that the great preventives, lemon and lime juice, were supplied and regularly issued as an antiscorbutic ration for the ships' companies when at sea. From that time to this lime juice has been constantly used, but its efficacy has disappeared. The reason for this has been ably shown by Mrs. Alice Henderson Smith. As originally prepared, the lime juice was made from sweet limes, *Citrus medica*, and with lemons, imported chiefly from Spain. In 1793 war stopped these supplies, but in 1802 delivery was resumed, and scurvy, which had obtained a temporary hold, was again almost eliminated. About 1860, by the development of the cultivation of limes in the West Indies, a large quantity was made available, and the contract for the navy caused the sour lime, *Citrus medica*, var. *acida*, to supersede the sweet limes and lemons formerly in use, and for a time this new lime juice was believed to be better than the old. This has been proved not to be the case, both by results of Arctic expeditions under Sir George Nares and by much recent laboratory experiment work.

I find that in 1793 Dr. Johan Kramer of Nuremberg, in the *Medicina castrensis*, said that it was useless to attempt to cure scurvy by drugs or by rubbing in applications to the affected joints, but recourse should be made to the acid vegetables of the garden, or, if these could not be obtained, lemons. The juice from the vegetables should be added as a watery solution to milk, or lemonade be made. These will bring about a certain cure.

There is no time here to enter into a full description of modern work on the action and characters of these essential vitamins, except to point out that one of the most important practical factors is their keeping power. The antineuritic is fairly stable—very stable if we are to believe the work of Jansen, who found that paddy of over one hundred years old, kept in storehouses in the higher regions of Java, was still as rich, or almost as rich, in anti-beri-beri vitamin as fresh rice. The antiscorbutic factor is, on the other hand, very much less stable, being easily destroyed by cooking, oxygenation, and keeping, especially in the presence of alkalis.

Though the antiscorbutic vitamin is generally so quickly destroyed by heating, there is the important exception in the case of tinned tomatoes; these, as originally shown by Hess, are still powerfully antiscorbutic, and are useful both for prevention and cure.

We know now that symptoms due to lack of vitamins are very slowly evolved, causing indefinite signs of ill

health and malnutrition, though in the tropics there is generally no deficiency of either the antiscorbutic vitamin C or the antirachitic vitamin A, yet in temperate climates these early symptoms are frequent in young children and are often not recognized. It is therefore good practice to reinforce the ordinary foods so often deprived of these three important vitamins. The food given should produce the minimum of heat but give sufficient nourishment. Proteins are physiologically less required, and we should follow out the example of the people of the country, who take more vegetable foods. If Europeans will insist on living as in a cold climate they develop all sorts of intestinal troubles and quickly run down.

It may be generally accepted that we need food from animal sources for the growth and maintenance of our body tissues; we need carbohydrates and fats for our body heat and energy, with inorganic salts to build up our tissues and perform physical functions; and lastly, we need an adequate supply of all vitamins, those substances without which there can be no healthy condition of the cells. If the consumption of the protein is in excess of the physiological requirements there is a tendency to gout and intestinal disorders, with an increased amount of work for the kidneys in eliminating the nitrogenous waste. An excess of fat tends to retard digestion of other foods; an excess of starch and sugar causes fermentation, with headaches and some forms of intestinal auto-inoculations and even a form of diabetes. People may appear well for a long period on a diet deficient in vitamins, but they will inevitably develop some form of constitutional disease, slowly evolved.

There seems to be little doubt that the water-soluble B, the water-soluble C, and the fat-soluble A vitamins have a definite place in a chain of reactions, which, if wanting, terminate in producing conditions known as beri-beri, scurvy, and rickets. Pellagra is also probably due to a deficiency of some protein factors.

#### IV.—JAMES WHEATLEY, M.D., County Medical Officer of Health, Shropshire.

##### THE PUBLIC HEALTH POINT OF VIEW.

THE extraordinary advances made in recent years in the knowledge of food, and particularly of food deficiencies, has placed a very great responsibility on that branch of the medical profession responsible for the health of the public. The magnitude of the responsibility rises in direct proportion to the importance of the advances made. It is obvious that, for practical purposes, these advances will be useless unless they are brought to the notice of the people in such a manner as to produce a real knowledge and a desire for better things, and unless facilities are provided for putting this knowledge into practice. These are the problems before us, and I venture to say that they will, in their way, prove as difficult of solution as any that have confronted the investigators into these food deficiencies.

The first essential is a general recognition of the supreme importance of health and of the extraordinary damage to health that is at present taking place through food deficiencies. Unless the thinking and influential part of the nation can be thoroughly imbued with these facts we shall not get the motive force to remove the obstacles—political, financial, social, and trade—at present standing in the way of progress.

The preceding papers will, no doubt, have dealt fully with the proofs we have of the bad effects of deficient foods. These proofs are mainly based on experiments on animals, and consequently have to be scrutinized very carefully. They have, however, been made on a great variety of animals, extending from monkeys to birds, by a large number of skilled observers, and on the whole with remarkable agreement. Moreover, in certain very important directions, they have been confirmed by the occurrence, prevention, and treatment of disease in man. It seems to me that we are justified in basing our preventive measures on the well established findings.

It will be useful to state concisely the supposed effects upon health of food deficiencies that have so far been investigated.

*Deficiencies of fat-soluble vitamins A, D, and E (?)*—in mothers' food causing stillbirths and premature births, marasmus, and general feebleness of infants, resulting possibly in a considerable proportion of deaths during the first month of life; defective growth of infant and child; infections of lungs, intestines, and eyes; rickets, and defective structure of teeth predisposing to caries; possible predisposition to enlarged tonsils and adenoids; and the train of symptoms associated with the catarrhal child.

*Deficiency of vitamin B*—loss of appetite, subnormal temperature, lowered function of the gastro-intestinal mucous membranes, resulting in inflammatory changes, constipation, and intestinal infections directly or indirectly causing a very considerable proportion of the illness after middle life; colitis, appendicitis, and gastric ulcers; lowered bactericidal power of the blood, and consequent lessened resistance to accidental infection; interference with growth.

*Deficiency in vitamin C*—infantile scurvy, greater susceptibility to infection, possibly interference with growth.

*Deficiency in calcium*, in addition to being an important factor in the production of rickets and defective teeth, produces certain important blood changes.

*Deficiency in iron*—anaemia; evidence of anaemia due to food shortage is not very obvious, except in persons kept on milk diet for long periods.

*Deficiency in iodine* is probably the basal factor in the causation of endemic goitre, and a cause of lowered general metabolism.

*Deficiency in roughage* has been assumed to be the important factor in causing intestinal stasis and the infections that follow from it. These results are now attributed largely to the shortage of vitamin B. Roughage probably has a value apart from the vitamins it contains—certainly as a compeller of mastication and probably by fulfilling a mechanical and perhaps an absorbent function in the intestines.

There seems good reason to think that a considerable part at least of this formidable array of disease, deaths, lack of growth, and vitality, can be caused by "food deficiencies." Have we sufficient reason for assuming that there is a serious deficiency of these substances in the diet of the people? We know that white bread, sugar, and margarine, forming perhaps 90 per cent. of the food of the lower wage-earning classes of our towns, contain almost no vitamins. We also know that rickets, an extremely common disease, is caused by a shortage of fat-soluble vitamin D, and that where there is a shortage of this vitamin there will be a shortage of vitamin A also. We may therefore safely assume that there is a widespread shortage of vitamins in the diet of the poorer classes. The causes of the deficiencies are ignorance, poverty, and the refinement of food over which they have no control.

These factors come into play very unequally with regard to the various deficiencies. The deficiency in fat-soluble vitamins A and D is largely due to poverty, but to some extent to ignorance. There is probably little deficiency of these vitamins in the foods of the well-to-do—possibly an excess. The deficiency in vitamin B is mostly due to refinement of cereals, or, for practical purposes, refinement of flour. No other food can adequately make good this deficiency where bread is as much as 70 to 80 per cent. of the diet. There is not the same deficiency where potatoes take the place of bread, particularly if the peel is eaten.

Unless we are prepared to make the pulses form a considerable part of our diet, or to substitute potatoes for bread or rye for wheat—and these alternatives are quite impossible—the shortage of vitamin B in the diet of the lower wage-earning classes can only be met by the consumption of wholemeal bread instead of white bread. This vitamin is contained in the germ and outer coats, and in the yeast used in making the bread. Of all our foods, yeast and wheat-germ are supposed to be the substances richest in vitamin B, and to contain this vitamin in about equal amounts. The germ forms only about 1.5 to 2 per cent. of the whole grain, while in baking bread dried yeast is added to the flour in a proportion of only about 1 per cent. It has been estimated that if these substances

are the only source of vitamin B in a diet, they should form about 6 per cent. of the total food. It has also been estimated that under similar conditions wholemeal flour should form 75 per cent. of the diet.

The wheat germ is about five times as rich in vitamin B as the outer coating, but whereas the germ only forms at most 2 per cent. of the whole grain, the outer part removed in the manufacture of white flour is equal to at least 20 per cent. of the whole grain. About two parts of the vitamin B in wholemeal flour is therefore due to the coatings, and one part to the germ. The vitamin B in wholemeal bread is due to the yeast (1 part), the germ (nearly 2 parts), and the coatings (4 parts). In other words, wholemeal bread contains about seven times as much vitamin B as white bread, when both are made with yeast. Mellanby's finding that wheat-germ, in the large quantities that he gave in his experiments, is a considerable factor in the production of rickets, has of course no bearing upon this particular question, but it shows how dangerous it is to fraction foods without scientific knowledge. If this simple fact had been understood in the past it would have saved us a great many very serious mistakes. Of the other cheap foods containing vitamin B, probably lentils in the form of soup is the best, and of the more expensive ones, eggs.

The deficiency in vitamin C is due to ignorance as to the value of fruit and the proper method of cooking vegetables, and also to poverty, for fruit and green vegetables are too expensive for daily consumption by the poorer classes unless they have productive gardens. Deficiency in calcium and in roughage is also due mostly to refinement, too much cooking, and rejection of all food difficult of mastication and digestion.

It may be accepted that there is a general shortage of calcium in our food, and that this shortage seriously affects a considerable proportion of our infants and young children. It is difficult to suggest how this shortage can be made good in a natural way. Milk and cheese are the foods richest in calcium, and when taken in any quantity there will be sufficient calcium in the diet. The consumption of milk per head in this country is, however, very small, and large numbers of poor children get practically none. The substitution of wholemeal bread for white bread would increase somewhat the amount of calcium in the food. Probably the amounts of calcium needed by the body at different ages and under different conditions of living have not been sufficiently worked out, but the needs of an adult have been estimated at from 9 to 16 grains. A growing child in the maximum bone-forming period would presumably require a considerably larger amount. The amount of calcium in 2½ lb. of bread, the quantity that will give sufficient calories for an adult, is only about 3½ to 4 grains if made of white flour, and about 5½ grains if made of wholemeal flour. So even if wholemeal bread is eaten, some food richer in calcium than bread should be eaten to make up the deficiency. A pint of cow's milk contains about 9½ grains of calcium, and would supply nearly the whole of the calcium required in a day's food. Half a pint of milk added to a diet deficient in calcium would probably, as a rule, make good the deficiency.

Experiments seem to show that inorganic salts of calcium can be utilized by the body. If this is so, the hardness of water is a matter intimately concerning public health. If 1½ pints of unboiled water of 20 degrees of temporary hardness were drunk daily, 1½ grains would be added to the daily intake of calcium. This would be only about 15 per cent. of the total daily requirement, but it would do something to make good the deficiency. There is, I believe, some difficulty in adding lime to soft water supplies. Perhaps, if necessary, this can be got over, but the question of deficiency of lime in our diet should certainly be considered when the adoption of any scheme of softening drinking water is contemplated. In these estimates the possible differences in absorption of lime in different states have been ignored.

Investigations show that the amount of iodine in the soil and in the plants and animals living on the soil diminishes generally with the remoteness from sea influences. There can be little doubt, too, that the lack of iodine is the basal factor in the production of endemic goitre, although this

conclusion does not exclude the possibility of many other influences in its production. It appears likely, too, that the lack of iodine in food is frequently responsible for lowered and disordered metabolism. On these assumptions it is clearly desirable that in some way the food supply of less favoured districts should be levelled up to that of the best. The addition of iodine in minute quantities to common salt appears to supply this deficiency in the most convenient way. When this question has been more definitely decided, Government action will undoubtedly be necessary to bring about the desired result in a reasonable time and in an effective manner.

It is obvious from this short statement that the removal of these deficiencies is going to be a very complicated task. It is quite clear, too, that our present food legislation, except that directed to the prevention of the use of preservatives, has no bearing on this question. The remedies are education and the provision of better facilities for getting suitable food.

The first step is education of the people so that they will have the requisite knowledge to get the best foods possible with the money available, and to prepare the food without damaging it. This should have a foremost place in health education and all our public health schemes, and schemes of propaganda should be utilized to the utmost.

Education of the elected bodies (Parliament and sanitary authorities) responsible for health is essential for rapid progress. The Ministry of Health might well give a lead to sanitary authorities by stating that it is most desirable that members of health committees should take every opportunity of making themselves acquainted with public health problems so as to be able to form a balanced judgement on, and appreciate the importance of, the matters brought before them by their professional advisers. They would then be able to put forward their recommendations with the requisite force and authority. Local authorities have great influence on Parliament, and are the training ground for members of Parliament, so that enlightenment of local authorities should react in time upon Parliament.

Education is the first and most important matter. It will not, however, get over the difficulty that the fat-soluble vitamins are contained almost entirely in the expensive foods—dairy produce, animal fats, eggs, and green vegetables; that vitamin B is refined out of the staple food before it reaches the public; that fruit is, generally speaking, too expensive for the town dweller; and that probably in every district there is a deficiency of calcium and in certain districts a deficiency of iodine in food.

It appears as if legislative action on entirely new lines will be necessary. Such action will only be possible if the proof of great damage to health by existing deficiencies is convincing. We are all greatly dissatisfied with the amount of disease and consequent suffering and inefficiency amongst us. The interference with the legitimate pleasures and enjoyment of life and the economic loss are appalling. If much of this is due to defects of food, and especially to "food deficiencies" in the special sense, the issue will be recognized as so important that legislation of a type hitherto unthought of would be demanded by the people. Such legislation might take the form of taxation of certain undesirable forms of food; or facilities for the greater production of others; or for the addition of substances to certain staple articles of universal consumption.

In order that the food supply should contain a sufficient quantity of vitamin B a tax might be put upon all flour containing less than a certain percentage of the whole grain. This would result in wholemeal bread being eaten by the large proportion of the population, whilst not prohibiting the manufacture of refined white bread for exceptional individuals who need special treatment. Or if the trade difficulties of storage are for the present almost insuperable perhaps these might be lessened by separating the germ, selling it separately, and making it compulsory for the bakers to mix a certain percentage of the germ with the flour. Or, as a very poor alternative for immediate action, it might be made illegal to sell wheat-germ for animal food. It would then be sold for human consumption, and could be retailed as biscuits, or in some other form, at a cheap rate.

Refined sugar is quite free from vitamins, and its excessive consumption, which there is much reason to think is injurious to health, might be lessened by a tax. The money saved on this food would then be spent on other more suitable foods, and the revenue raised might be used for cheapening other and better foods.

The problem of placing the lower wage-earning classes in a position to get a good supply of the fat-soluble vitamins is a very difficult one. The radical solution of increased earning power will, no doubt, come gradually along with increased production. In the meantime, what legislative or other measures are possible, apart from education, to enable poor persons to get a better supply of these vitamins?

Everything points to the fact that the principal damage is done during the first few years of life. A point that requires further elucidation is: Up to what age is a plentiful supply of fat-soluble vitamins essential? If we are correct in assuming that there is a marked shortage of these vitamins in the diet of young persons of the lower wage-earning class, particularly in the towns, due largely to economic reasons, and that in practice the deficiency can only be removed by an increased consumption of dairy products, principally milk, it follows, I think, that the only immediate remedy is a great extension of the scheme for supplying milk to expectant and nursing mothers and young children. In addition, the Government should give every encouragement possible to the increased production of milk and green vegetables and the cheapening of their distribution. It is upon a plentiful and cheap supply of these foodstuffs that the health of the nation largely depends, and consequently economic reasons should not entirely prevail. We know that the ordinary economic laws affecting the production of commodities are constantly interfered with, but never, or almost never, for the purpose of improving health. Why not?

The country population should be safeguarded by a simple enactment making it a *statutory duty* of dairy farmers to supply milk to the inhabitants of their district at a price between the wholesale price and the retail town price, and encouragement should be given to cottagers with proper facilities to keep goats. These measures would, to some extent, get over the extraordinary difficulty, probably an increasing one, of obtaining milk in many country districts. The facilities for allotments should be greatly increased, and sufficient garden should be provided to every new house for growing vegetables and fruit.

Further legislation is necessary to prohibit the treatment of milk in such a way as to cause any considerable diminution of the vitamin content, and every possible step should be taken to see that a milk is produced that will gain public confidence without increasing the price. Further legislation may prove to be necessary to prevent the destruction of vitamins in the canning and other methods of preservation of all classes of foods.

Not sufficient attention is paid to the quality of dairy products and the desirability of increasing grass feeding to the utmost. Imported butters from different parts of the world must vary enormously according to the season—whether the grass is growing well or the land is under snow. In particular, New Zealand butter must be vastly superior to Danish during the months of November, December, January, February, and March.

Whether, if all these measures fail to meet the situation, we shall have to fall back upon some artificial method of providing vitamins or other substances in a concentrated form and distributing them in common foodstuffs remains to be seen. It is to be hoped that no such measures will be necessary, but if they prove to be, then the compulsory addition of fat-soluble vitamins to margarine appears to be the most practicable application of this method.

If it is established that the lack of vitamins A and D in the food of the expectant and nursing mother and the infant is one of the causes of premature births, stillbirths, feebleness at birth, *marasmus*, deaths of infants during the first month, rickets, and bad development of jaws and teeth, it follows that ante-natal work is one of the most important and will be one of the most fruitful of our public health activities: also that the branch of this work concerned with the detection of abnormalities and the prevention of dangers from them, which has formed so

large a part of ante-natal work, although very important, sinks into insignificance compared with the careful supervision of the general health of the expectant mother. To be effective it must be accompanied by a liberally administered scheme for the supply of milk.

Although our knowledge of food deficiencies has made wonderful strides, there is much need for further research, and it is most encouraging to see that this, probably the most important work that has ever been done to improve the health of a people, is being undertaken with great vigour throughout the civilized world. We want more definite information and particularly of a quantitative nature. What is the optimum amount of the vitamins for different body weights, ages, and total food quantities? Can harm be done by excessive amounts of vitamins? Does the necessity for fat-soluble vitamins almost disappear with cessation of growth? What is the actual shortage of vitamins in the foods of different classes of the population—those in which money and knowledge are scarce and those in which there is no shortage of money for food and knowledge may be supposed to be more advanced? An inquiry of this kind was commenced under the auspices of the Society of Medical Officers of Health by Dr. Daley at Blackburn, but owing to industrial disturbances, which would have rendered the inquiry almost useless, it was abandoned and has not since been attempted. Inquiries of this description that have so far been made appear to me to be very inconclusive.

The Essex investigation, so far as it went, seemed to show that there was no marked food deficiency amongst the country children inquired into. These results cannot be applied generally without far more extensive and complete inquiry, but they do show the extraordinary public health importance of the cottage garden.

Such inquiries seem to me to be absolutely essential and urgently needed, if we are not simply to continue guessing at the amount of vitamin deficiency and the damage done.

Notwithstanding the necessity for further investigation, the proof that food deficiencies are causing an enormous amount of ill health, lack of growth, and premature death, is to my mind conclusive, and a study of the present position of the food supply of the people leads me to the inevitable conclusion that Government help in the way of special legislation and financial aid in certain directions is essential, unless we are prepared to wait for improvement until the people have been sufficiently educated and their earning power sufficiently increased. Has not the time arrived when the Government should take this matter up seriously with the object of encouraging the greater production of those essential foods which are at present too dear for the masses, and rendering available those natural foods which have been refined almost out of existence?

Can anyone doubt the economy of such expenditure?

#### GENERAL DISCUSSION.

Dr. GREENFIELD (Rushden) said he thought many observers had failed to notice the prevalence of rickets among the agricultural population. It had been stated that the grosser manifestations of food deficiency were found very rarely in the country, but it was only in recent years that the minor symptoms of thyroid deficiency had been recognized. Enlarged tonsils, adenoids, and pyorrhoæa were apparently more prevalent in this country than abroad, and he believed these conditions were all attributable to errors in diet. The prevention of pyorrhoæa and streptococcal invasions of the mouth would be one of the greatest advances which modern medicine could make.

Professor LEONARD HILL observed that cod-liver oil had been used for many years, and, having gained a great reputation in the treatment of tuberculosis, must have been effectively prescribed. It had not, however, acquired that reputation for preventing and curing rickets and tuberculosis which it would have gained in that period of years had it possessed the powers now claimed for it. Ultra-violet rays were required to balance the loss of sunlight in cities and to give that aid which had been found to be so valuable in country sanatoriums in the curative

treatment of tuberculosis and rickets. Light acted not only by the ultra-violet rays, which by activating cholesterol formed the antirachitic vitamins, but also by rays of longer wave-length, including visible rays. The energy of these rays was sufficient to penetrate the epidermis so that it could be converted by the blood and the living cells of the tissues. Open-air and light treatment must in all cases be combined with a diet rich in vitamins.

Dr. B. SPEARMAN (Zanzibar) said it had often been stated and published in the press that the primitive savage was the physical ideal to which they must look. After many years' intimate experience of primitive African tribes in Uganda and Zanzibar he was compelled to dissent from that view. The African native was on the whole a fine fellow physically, but his resistance to infections was low. He was prone to suffer from coughs and "colds" and more serious respiratory diseases, from ophthalmia, and from a peculiar form of chronic and indolent ulcer which was extremely difficult to cure, even when modern methods of treatment in hospital had replaced the universal native panacea—cow dung! His resistance to epidemic diseases such as small-pox and cerebro-spinal meningitis was extremely low, but rickets was unknown among these tribes, probably because of their liberal supply of sunlight. Rickets was occasionally seen in Zanzibar, but almost always among Indian females living under the purdah system, which involved deprivation of light and air. He was, however, satisfied that many of these people suffered from disorders due to food deficiency. Different tribes had different diets, consisting mainly of maize, millet, bananas, or sweet potatoes. In all cases these diets were traditional, unvaried, and monotonous, and he believed they could be shown to be seriously deficient in the accessory food factors.

Dr. B. DUNLOP (London) supported Dr. Greenfield's view that there was a considerable amount of rickets among the inhabitants of rural areas, and that it was due to diet deficiencies. Like urban populations, they lived too much on white bread and tinned foods, but he thought that people could be well fed without milk. He was glad that it had been pointed out that the natives of tropical climates also suffered from food deficiency conditions, but thought that any physical superiority they possessed was due to eugenic selection, which prevailed more among such people than it did at home. The discussion supported the idea that the nation should breed mainly from people who could afford to supply an ample diet and sufficient air and sunshine to their children.

Dr. H. SCURFIELD (Folkestone) thought that a large section of the population of our industrial towns were very short of the foods enumerated by Dr. Mackay as the chief sources of vitamin B. There was accordingly a real danger of lack of this vitamin in the national dietary, and he believed that much of the prevalent constipation, dental decay, and stunted growth was due to a deficiency of vitamins. The results reported from the artificial light treatment of tuberculosis were very conflicting. With regard to Dr. Wheatley's suggestions, he thought the first step should be to secure legislation which would enable the purchaser to know what he was getting when he bought bread or flour—that is, the proportion of bran, germ, and endosperm in the article purchased. He hoped the Medical Research Council would shortly investigate the vitamin content of jam and marmalade.

Professor F. E. WYNNE (M.O.H. Sheffield) pointed out that Mellaub's researches were not confined to experiments on animals. They were tried out in the children's wards of the Sheffield Royal Infirmary and at the Child Welfare Centres. The administration of cod-liver oil cured rickets, in his experience, with the precision of a laboratory experiment. He did not at all underrate the value of sunshine and the other factors involved in the life of almost nudity lived by tuberculous children in their Sheffield hospitals, but their results from artificial ultra-violet light had not quite confirmed the enthusiastic reports received.

from other places, and to apply it to all children in a large industrial centre was, in existing circumstances, a financial impossibility. The difficulty in connexion with rickets was to get hold of the cases. He saw many cases in the slum districts, but mothers refused to admit that there was anything wrong with the children. He could not understand the attack that had been made on sugar as an article of diet, and believed that the child's craving for sugar represented a physiological need.

Dr. E. V. ASHCROFT (Manchester) said that twelve years' experience in Ancoats, which was largely a slum district, had convinced him that the incidence of rickets depended not so much on food deficiency or deprivation of light as on want of cleanliness. He described the treatment of rickets carried out at the Greengate Hospital, Salford, which consisted of cleansing the children and the administration of cod-liver oil. He attributed the excellent results obtained mainly to cleanliness.

Dr. STUART COWELL, in replying to the discussion, said that he and those associated with him fully appreciated the value of light in the prevention and treatment of rickets and other deficiency diseases, but he was satisfied that light could only operate satisfactorily when there was an adequate supply of vitamins in the diet.

Dr. WHEATLEY said he could not accept Dr. Wynne's suggestion as to instinct as a guide in these matters. Instinct might be a reliable guide under natural conditions, but was not to be trusted in artificial ones. Under natural conditions sugar was difficult to obtain, and the craving for it led to the consumption of fruit. To satisfy this craving by resort to artificially refined sugar was unnatural and dangerous.

## THE SECTIONS.

### BRIEF SUMMARY OF PROCEEDINGS.

ARRANGEMENTS have been made to publish, during the next few months, full reports of the discussions in the Sections of the Annual Meeting at Nottingham. Meanwhile, the notes printed below will enable members who were not present to gain a general view of the proceedings. Any errors to which attention may be drawn will be corrected in the full reports.

### SECTION OF MEDICINE.

Wednesday, July 21st.

#### THE BILIARY TRACT.

PROFESSOR EVARTS GRAHAM opened a discussion on "Some recent developments in our knowledge of the biliary tract." After a short statement on the functions of the gall bladder Professor Graham discussed the pathogenesis of cholecystitis, and, turning to diagnosis, said he would only deal with cholecystography. A proper conception of the interpretation of cholecystography must be based on an understanding of some of the theoretical points involved. The substance used must be excreted by the liver into the bile; it must pass with the bile into the gall bladder, and there it must be concentrated by the absorption of water in order to give the densest shadows. It was thus apparent that the densest shadows would be in normal subjects, whereas there would be no shadow at all, or only a faint one, if the liver was unable to secrete the substance, if the cystic duct was occluded, or if the gall bladder was unable to concentrate its contents owing to a diseased wall. The method provided a means of investigating the only two known functions of the gall bladder: its distensibility and contractility were shown by alterations in the size of the shadow, its power of concentration by the density of the shadow. The interpretation of results depended in part on the technique adopted, and Professor Graham discussed shortly the advantages of the intravenous and oral methods and of the various salts used. He himself preferred the intravenous route, and used either tetraiodophenolphthalein or its isomer phenoltetraiodophthalein; and he gave a

detailed account of his own technique. The chief points in making a diagnosis of cholecystic disease were: (1) Failure to obtain a shadow. (2) Filling defects; soft calculi were frequently seen as "negative" shadows, and many small stones often produced a characteristic mottled appearance. (3) Irregularities of contour denoting adhesions, diverticula, etc. (4) Variation from normal in the density of the shadow or in the time of its appearance or disappearance; these were the most difficult to interpret. He had had no alarming symptoms in the last 500 cases. He gave a tabulated list of the degree and number of reactions experienced with different drugs and methods of administration. Finally, he discussed the mechanism of emptying the gall bladder. Muscular contractions of the wall seemed to play only a very minor part, the chief factors being apparently the elastic recoil of a distensible viscus, the washing out of the organ by the ingress of fresh hepatic bile, and intra-abdominal pressure.

Dr. Hurst said that 10 per cent. of all dead bodies showed the presence of gall stones; these were all preceded by cholecystitis, but as cholecystitis was not necessarily followed by gall stones it must be even more common, and occurred probably in at least 20 per cent. of all persons. He urged the need for early recognition so as to prevent the formation of stones. Flatulent dyspepsia was frequently due to cholecystitis, and such cases should be examined by a diagnostic team, which should exist in all towns. The three most important diagnostic methods were: (1) Test meal; 50 per cent. of cases of cholecystitis showed achlorhydria or hypochlorhydria. (2) The duodenal tube; this might show evidence before the cholecystogram. (3) X rays and cholecystography, as in the case of appendicitis he found the presence or absence of tenderness over the visualized organ a most helpful point. Cholecystitis was an infective disease, and the main treatment was sterilization of the gall bladder by urotropine in large doses up to 100 grains three times daily if alkali was given with it in sufficiently large doses to keep the urine alkaline; in the case of the gall bladder the drug acted even in an alkaline fluid. Dr. F. A. Knott gave the result of his experience with the Einhorn tube; he emphasized the need for examining a series of upper alimentary specimens rather than the duodenal contents only. With regard to the power of urotropine in sterilizing the bile, he suggested that one factor might be the lowering of surface tension. Professor D. P. D. Wilkie testified to the extreme usefulness of cholecystography and the increased accuracy in diagnosis obtained by its use. He preferred the intravenous route, but the drug must be freshly prepared and scrupulous care in technique taken. Although they might have to modify their views of gall-bladder activity in the light of Kodama's work, he found it difficult to believe that the muscular wall and rich nerve supply had nothing to do with it. Mr. C. F. W. Illingworth described the technique adopted, and gave the results of his work in conjunction with Professor Wilkie, with illustrative slides. Dr. J. W. McNea discussed the changes in the biliary secretion passing along the bile passages. Cholesterol was, in his opinion, not formed in the wall of the gall bladder; it was derived from the food, absorbed as cholesterol esters and passed through the liver cells; there it was de-esterized, and entered the bile as pure cholesterol; passing into the intestine it was re-esterized and absorbed, so that it was conserved in the body with the same care that iron was.

Dr. T. Izod Bennett spoke of the clinical aspects of diseases of the biliary tract. In cholecystography he used the oral route of administration, which avoided any risk of venous thrombosis. His last fifty cases had been uniformly successful, and toxic symptoms had not been grave. Dr. J. H. Anderson gave the results of his series of cases of cholecystography, illustrated by slides. He used the oral route now in nearly all cases with quite satisfactory results; he also gave a barium meal so that the relative position of the gall bladder to the alimentary canal might be more easily determined. Sir Berkeley Moynihan paid tribute to Dr. Graham's pioneer work. He believed a high blood cholesterol figure to be of great importance. In early cases of cholecystitis there was a cholesterol flood with high cholesterol content in the blood, bile, and walls of the gall bladder. In chronic cases, on the other hand, the calcium

content was high. Sir Humphry Rolleston, after a tribute to Dr. Graham, doubted whether they would ever reach Dr. Hurst's ideal of being able to dispense with the surgeon in cases of cholecystitis. He agreed that there was little evidence of contractile power in a healthy gall bladder. Dr. Graham replied briefly.

#### SECTION OF SURGERY.

*Wednesday, July 21st.*

GREAT regret was felt that illness prevented Sir D'Arcy Power from presiding at this Section, and the hope was expressed that he would speedily regain his health. His place was taken by Sir James Berry.

#### CEREBRAL TUMOURS.

The discussion of cerebral tumours centred chiefly round general problems. There was general consent that cerebral surgery required very special training. Many speakers emphasized the frequency of tumours of the brain, and stressed the necessity for complete neurological investigation of every case where the symptoms suggested in the slightest degree the presence of such a condition. Mr. Percy Sargent, who opened the discussion, was able to show from his experience that the outlook for victims of this disease was not so gloomy as was generally depicted. Of 300 operations for glioma, for instance, 25 per cent. of the patients returned to work after the operation. In other brain tumours a similar degree of success was obtained also. Mr. A. P. Bertwistle (London) communicated a method for localizing more accurately the sulci from without the skull. Mr. G. Jefferson (Manchester) urged the need of more intensive study and specialization by surgeons in neurology, and claimed good results from operation. Mr. J. P. Ross (London) spoke of the danger from increased intracranial tension after operation and its relief. He referred also to the results of radiotherapy. Mr. H. S. Souttar (London) demonstrated an ingenious instrument for turning down rapidly an osteoplastic flap. The whole discussion gave a different complexion to the generally accepted view of the almost hopeless prognosis in brain tumour.

#### THE PLACE OF GASTRO-ENTEROSTOMY.

The discussion on the place of gastro-enterostomy in the treatment of simple ulcer appeared inconclusive. Mr. H. Paterson (London) was a strong upholder of the operation, while Professor H. Finsterer of Vienna was equally emphatic in denouncing it. There was no general agreement as to how the operation acted as a curative measure, nor how it should be performed. Mr. K. W. Monsarrat (Liverpool), Mr. C. Roberts (Manchester), Dr. H. Bruce (Toronto), in the main supported Mr. Paterson. Mr. E. Deanesly recommended Finney's operation as a substitute in duodenal ulcer. Professor D. P. D. Wilkie (Edinburgh) favoured local resection with gastro-jejunostomy for gastric ulcer, while Sir William Wheeler (Dublin) advised resection. He also declared that the sleeve operation was not so successful as he had once believed. Mr. A. B. Mitchell (Belfast) for gastric ulcer recommended gastro-jejunostomy with infolding; for a bleeding duodenal ulcer ligation of the pancreaticoduodenal artery was advised.

*Thursday, July 22nd.*

#### CARCINOMA OF THE TONGUE.

The treatment of carcinoma of the tongue was first discussed, and the result of the morning's debate was to show that finality had not been reached on this question. While Mr. D. C. L. Fitzwilliams, who opened the discussion, pleaded for the use of the knife whenever possible, other speakers, including Mr. Gordon-Taylor, recommended the diathermy cautery. Other debatable questions were the dissection of one or two sides of the neck to remove the lymphatics and the order in which operations should occur. Mr. W. S. Dickie (Middlesbrough) described a useful method of extirpating growths at the base of the tongue, and exhibited two patients upon whom the operation had been performed. Sir William Milligan spoke of the results of diathermy and radiation therapy, and claimed that

51 patients out of 812 were cured. He included apparently all forms of cancer of the buccal cavity in these statistics. Mr. Gordon-Taylor admitted a very considerable mortality from operation, but gave a hopeful account of the subsequent course of events—namely, 50 per cent. of cures. Several speakers emphasized the danger of death from bronchopneumonia, which Mr. Stanford Cade said could be eliminated by employing local anaesthesia only.

Mr. H. W. Carson read an interesting short paper on the after-treatment of carcinoma of the breast, which provoked some discussion. Mr. A. B. Mitchell gave a lantern demonstration of methods of treating spiral fractures and dislocation at the acromio-clavicular joint.

#### SECTION OF OBSTETRICS AND GYNAECOLOGY.

*Wednesday, July 21st.*

#### TERMINATION OF PREGNANCY BEFORE VIABILITY OF THE CHILD.

Dr. T. W. EDEN, opening the discussion on the indications and methods for termination of pregnancy before the viability of the child, thought that from time to time they should consider what conditions could be agreed upon as indications for the induction of abortion. Each case deserved sympathetic consideration on its merits. Dr. Eden thought that it was an ethical question of great interest to what extent they, as doctors, had the right to insist that a woman should pass through an ordeal which she was unwilling to face, even if they did not think that she would sustain any permanent injury from so doing. At times it might be right to terminate pregnancy even if the mother were not suffering from any condition which might strictly speaking be called disease, but only after the most careful consideration. Dr. Eden then gave the chief medical indications for the induction of abortion. In regard to phthisis there was much difference of opinion. Generally speaking there was not much risk to the mother in healed or arrested cases if her physique were good; but in active disease pregnancy usually hastened the tuberculous process. He advocated a close association between the obstetrician and the physician before determining whether induction should be performed or not. As regards the chances of life of children born to a phthisical mother, Dr. Eden said that in France it had been estimated that 38 per cent. of such infants did not survive the first month. Dr. Ward, the tuberculosis officer for South Devon, had estimated that the children of a tuberculous mother were seven times more likely to become themselves tuberculous than the children of healthy mothers. Of tuberculous women who became pregnant, Dr. Ward estimated that 50 per cent. were definitely worse, while 19 per cent. were improved. Dr. Eden considered these to be powerful arguments for the termination of pregnancy in women who were the subjects of active tuberculosis. In chronic nephritis the risks of pregnancy were considerable, both to mother and to child. The speaker suggested that a woman with chronic interstitial nephritis (azotaemic type) should be allowed to continue with her first pregnancy under supervision, but in subsequent pregnancies abortion should be induced early if serious renal breakdown occurred in the first pregnancy. The early occurrence in pregnancy of albuminuria with oedema justified (if it did not urgently demand) the induction of abortion. Induction might become necessary in some cases of *B. coli* infection of the urinary tract. With the introduction of insulin the risks of pregnancy in diabetes mellitus had been very greatly reduced, though not entirely eliminated. In valvular disease of the heart induction of abortion was right when there was failure of compensation in the early months and in cases where serious breakdown had occurred in a previous pregnancy. Pregnancy in an insane patient might have to be terminated, but only after consultation with a psychiatrist. Induction was hardly ever necessary in chorea, but now and then an exceptional case of psychopathic disturbance might render induction advisable. Dr. Eden then dealt with the obstetric indications. Toxaemic vomiting sometimes proved incurable by medical means and pregnancy had to be terminated. These cases were relatively of very rare occurrence. Induction should not be contemplated in the non-toxaemic forms of hyper-

emesis. Cases of vesicular mole and missed abortion should be treated by evacuation of the uterus as soon as the diagnosis was made. Free bleeding in the early months did not in all cases result in abortion. Persistent bleeding was of far more serious import to the life of the ovum than an initial smart haemorrhage.

Mr. J. D. Barris described the different methods whereby pregnancy could be terminated. The method selected should cause the least amount of strain or risk of injury. The factors to be considered were the urgency of the need for termination and the date of the pregnancy. As a rule the need for rapid evacuation was more insistent before the third month, therefore a rapid method was the one called for and was the one most likely to give a good result. After the third month the risk of delay was not of such import as a rule, and the difficulties attending upon a rapid evacuation of the uterus were such as to render a slower method far more preferable, even though such methods were not always immediately reliable and might have to be repeated. If the need for a rapid evacuation after the third month was urgent Mr. Barris advocated a vaginal hysterotomy. He had found Caesarean section very satisfactory in cases of vesicular mole. He reviewed briefly the different methods which could be employed according to the circumstances of individual cases. Professor Louise McIlroy thought that induction should only be performed in the direst necessity; with increasing knowledge there would be a reduction in its employment. Referring to the ethical aspects of the question, she was opposed to the induction of abortion unless the continuance of pregnancy was going to subject the patient to a very grave risk. She favoured sterilization by x rays in tuberculosis. In some heart cases pregnancy was beneficial, since it compelled the patient to take much needed rest. She preferred slow induction whatever the date of gestation was. Vaginal hysterotomy or Caesarean section she was entirely opposed to when a living child was not the object sought after. Dr. F. W. Price dealt with the subject from the point of view of the cardiologist, and urged that pregnancy should not be terminated until a reasonable period of rest and appropriate treatment had been tried. Dr. R. H. Cole mentioned the various types of mental aberration which might be complicated by pregnancy, and on the whole thought that induction should only very exceptionally be undertaken in this type of case. Dr. R. A. Young thought that in tuberculosis the induction of abortion might be as harmful to the patient as a natural labour. The circumstances of every case ought to be very carefully considered by the family doctor, the obstetrician, and the physician in consultation. He would consider the advisability of abortion in the presence of very active disease, but not in cases of the quiescent or arrested type. Pregnancy should not be allowed to interfere with treatment. A useful aphorism was that prevention was better than abortion. Dr. R. C. Buist pleaded that general practitioners should not send their cases to the specialist with a final opinion already expressed. Dr. Henry Evers insisted that induction should never be performed for purely speculative reasons. Dr. Binnie Dunlop held strongly that in the public interest the profession should be free to terminate pregnancy on economic or eugenic grounds as well as for purely medical reasons. Dr. English explained the method of inducing abortion by passing a stomach tube into the uterus. Mr. L. C. Rivett had found in a rather limited experience of tuberculosis that the puerperium was the time of danger whether full term had been reached or not. He commented on the serious effects of extreme heart failure in pregnant women even after delivery, and spoke favourably of Caesarean section with ligaturing of the tubes in selected cases of heart disease. Mr. Norman Lock thought that Caesarean section was a less severe ordeal than natural labour. The President (Mr. Comyns Berkeley) emphatically protested against a patient being told that she should never again have another pregnancy. He supported the view that rapid methods should be employed in the earlier months and slow methods in the later months, owing to the difficulty and danger of the rapid methods. The discussion had brought out the great value of team work. The discussion was brought to a close

by Professor McIlroy, Mr. Barris, and Dr. Eden, who urged the profession to take a broad view of its responsibilities in the matter of inducing abortion.

#### SECTION OF NEUROLOGY AND PSYCHOLOGY.

Wednesday, July 21st.

On the first day a joint meeting was held with the Section of Ophthalmology, Dr. Farquhar Buzzard in the chair. Professor Edwin Bramwell (Edinburgh), for the Section of Neurology, opening a discussion on migraine, described the various symptoms associated with an attack and the manner in which they might vary in different cases. He also referred to the close analogy between many of the symptoms of epilepsy and those of migraine; in his experience, however, the resemblance was superficial and the two conditions seldom met with in combination. He considered that the most reasonable explanation of the headache was spasm of the meningeal vessels, giving rise to the prodromal symptoms, followed by dilatation, which produced the headache, so frequently described as throbbing in character. Professor Bramwell then reviewed the different theories regarding the etiology of migraine, and also referred briefly to treatment. Mr. H. McMullen (London) opened for the Section of Ophthalmology. From his standpoint the visual symptoms were the most interesting, and they were also the commonest subjective phenomena associated with migraine. They consisted of spectra, whirling spheres, zigzags, scotomata, and more rarely visual hallucinations. Loss of vision in the upper or lower half of the visual field might also occur, and total loss of vision had been recorded. He described the rarer form of migraine, in which ocular palsy occurs (migraine ophthalmoplégique), stating that in many cases an organic lesion of the affected oculomotor nerve had subsequently been found. As regards eye-strain as an etiological factor, the matter was still uncertain, and diametrically opposed views had been expressed by different writers. In his experience the refractive error was usually slight, and many cases derived undoubted benefit from its correction. Dr. Walter Timme (New York) dealt mainly with the role of the pituitary gland in the causation of migraine. In his opinion migraine was merely a symptom of an underlying condition, and not a disease *per se*. Migraine might be the result of eye-strain or other forms of irritation. He particularly wished to emphasize that one type was due to compensatory enlargement of the pituitary gland. If the sella turcica were small, such enlargement would produce headache, and might eventually lead to an erosion of the bone demonstrable upon x-ray examination.

Dr. Gordon Holmes (London) regarded migraine as a definite clinical entity although it was frequently confused with conditions which merely resembled it. In his opinion the evidence of physiology which demonstrated the absence of vasomotor fibres in the cerebral vessels was against the hypothesis of a vasomotor disturbance being responsible for the symptoms. Also, the onset of attack was too rapid to be accounted for by pituitary enlargement.

Dr. R. G. Gordon (Bath) dealt with the mental state in sufferers from migraine and the analogies to that met with in epilepsy. Psychological investigation often revealed compensations for a feeling of inferiority. He also referred to the rare occurrence of automatism following migraine. Dr. E. I. Spriggs (Ruthin) had found that cases which appeared to be examples of true migraine were often associated with a definite physical disorder such as gall stones or constipation. Relief of such disorder had been followed by disappearance of the migraine. Dr. W. A. Potts (Birmingham) referred to the association of hyperglycaemia and migraine. In such cases barley-sugar had given relief. Dr. G. E. Nesbitt (Dublin) dealt with his personal experiences of migraine. It was difficult to assign a cause for the vaso-dilatation and equally difficult to explain why, if the pituitary gland enlarged, other endocrine organs did not similarly enlarge. Mr. E. W. Brewerton (London) knew of a case relieved during the attack by the application of heat to the occipital region during the actual attack. Dr. C. Worster-Drought (London) dealt with his experiences in

treating migraine; he had found that luminal (grain 1/2) given twice or three times daily over a long period was probably the best remedy for averting attacks. He also referred to the occurrence of unilateral dilatation of the pupil during the paroxysm.

## SECTION OF LARYNGOLOGY AND OTOTOLOGY.

Wednesday, July 21st.

### TREATMENT OF MALIGNANT DISEASE OF THE UPPER AIR AND FOOD PASSAGES.

THE discussion at the first session, with Dr. Brown Kelly (Glasgow), President of the Section, in the chair, was on the treatment of malignant disease of the upper air and food passages, and was opened by Mr. F. J. Steward (London) from the point of view of the surgeon. He said that in the selection of patients for operation, they fell into the three groups of favourable, doubtful, and hopeless cases. The first was a small group, including 10 per cent. of the total, or less; doubtful cases made up about 50 per cent. of the total. About 4 in every 10 cases which he saw were obviously hopeless, either on account of the extent of the primary growth, or of the glandular involvement, or both; but a purely palliative operation might be indicated. The principal dangers and complications of these operations were the result of infection of the operation wound or of the lungs; these complications were more frequent and serious when the teeth were septic. The anaesthetic which he had used for many years in all major operations on the nose, mouth, and throat was ether administered by intratracheal insufflation. It was usually convenient to remove first the lymphatic glands and vessels. The growth might be dealt with by excision or diathermy; the principal advantage of the latter was that the peripheral coagulation sealed off the surrounding tissues. The result of the whole operation depended largely upon the successful closure of the opening into the pharynx.

Dr. Robert Knox (London) discussed the subject from the point of view of x-ray treatment. Recent improvement in technique had brought the possibility of administering a satisfactory dose of x rays in these cases perceptibly nearer; higher voltages enabled the radiologist to apply a greater intensity at the depth, while working at a greater tube distance, with filters on the skin of 2 to 10 cm. of wax, aided in the giving of a strong dose in the depth with no risk of skin damage. Accurate diagnosis was essential; it was often the secondarily affected glands which first called attention to the disease, and it had to be settled whether the glands were primarily or secondarily affected, thus necessitating a careful search for a primary lesion. In doubtful cases, when a primary lesion could not be found, a few x-ray treatments might indicate the nature of the disease. He commended the conservative use of x rays in combination with surgical measures as early as possible; in cases where surgical removal was possible, but there was widespread glandular involvement, pre-operative treatment was to be advocated. In inoperable cases x rays might be extensively employed to alleviate symptoms.

Sir William Milligan (Manchester) took up the subject from the point of view of treatment with radium, and said that he was compelled to confine his remarks almost exclusively to the treatment of surgically inoperable growths, since few surgeons had the courage to employ radium where the growth appeared to be removable by ordinary surgical procedures. In the treatment of inoperable carcinomata some believed in large doses and short exposures, while others advised small doses and long exposures. In the majority of cases the speaker favoured treatment by small doses and long exposures up to ten, fourteen, or even twenty-one days. Radium was useful for its devascularizing effects before surgical intervention, while the uncertainty of effecting complete removal by surgical measures, combined with the risk of serious haemorrhage and the possible occurrence of severe septic otitis media, rendered its employment practically free from risk, apart from occasional perforation of the palate or necrosis of the bony walls of the posterior choana. The

more fibrous the growth the larger was the dose and time required. It was a moot point whether glands should be removed before the operation upon the primary growth. In malignant growths of the larynx, extrinsic growths might be successfully approached *per vias naturales* with the aid of Haslinger's directoscope; but in cases where the growth had extended laterally it might be advisable to expose the wall of the deep laryngo-pharynx from the outside. Malignant disease of the oesophagus was one of the saddest and most difficult surgical problems, largely because the cases were seen too late. The fetish of "nervous symptoms" and the vogue of the bougie—a dangerous and inconclusive instrument—still dominated too many practitioners. Treatment of this condition was enormously helped by the performance of a gastrotomy, which gave physiological rest to the affected part.

Dr. W. S. Syme (Glasgow), dealing with treatment by diathermy, said that for more than seven years he had made use of diathermy in the treatment of malignant disease of the mouth and throat—at first timidly and only as a palliative measure in inoperable cases, but later operable cases in all stages had been dealt with. Sometimes a preliminary tracheotomy was performed. Ordinary principles such as removing diseased teeth should not be neglected because diathermy was being employed. Chloroform was necessarily the anaesthetic employed, ether being obviously contraindicated. The extent and the position of the disease had to be considered in deciding to employ diathermy. Broadly speaking, the method decreased in suitability as the site of the disease descended from the alveolus to the oesophagus. Even in advanced and inoperable cases this method of treatment could give some measure of relief to nearly all patients.

## SECTION OF ANAESTHETICS.

Wednesday, July 21st.

### THE FUTURE OF ANAESTHESIA.

ON Wednesday, July 21st, the first discussion in the Anaesthetics Section, under the presidency of Dr. Samuel Johnston (Toronto), was opened by the President with an address on the future of anaesthesia. Dr. Wesley Bourne (Montreal) followed with a paper on the effect of some impurities in ether on respiration. Dr. H. M. Cohen, in a short address, described the value of journals, current literature, and year-book to the science and art of anaesthesia, while Mr. C. W. Moots (Toledo) was emphatic on the necessity of co-operation with the surgeons. Dr. A. L. Flemming (Bristol) continued the interest by contributing a paper on preventing needless deaths. An interesting discussion followed, in which many overseas visitors took part, as well as a member from Ireland and the President-Elect for the following year, who, although a physician, claimed that he was of the fraternity, since anaesthetists were primarily physicians and only secondarily the allies of the surgeons.

In the afternoon a discussion on the newer gas anaesthetics was opened by Dr. F. H. McMechan (Avon Lake, Ohio), in which he was followed by Dr. E. I. McKesson (Toledo), who discussed guiding signs and dangers. Many speakers took part in the discussion, both from home and overseas, and it was late before the President declared the meeting closed.

Thursday, July 22nd.

### ANAESTHESIA IN CARDIO-VASCULAR AFFECTIONS.

THE third session, in the morning of Thursday, July 22nd, was opened by a cardiologist (Dr. F. W. Price), in a paper on cardio-vascular affections. He endeavoured to convert all anaesthetists into competent cardiologists by summarizing the chief points in cardiology which were of interest to the practising anaesthetist. Dr. J. Blomfield followed with a paper on anaesthesia in relation to cardio-vascular affections, which summarized the problem from the point of view of the anaesthetist. Dr. Ernst von der Porten followed, and an animated discussion ensued, in which numerous speakers took part. The general trend of thought was that while valvular conditions could for the most part be disregarded if compensation was good, cardio-

vascular lesions were of great importance in the choice and in the desirability or otherwise of giving an anaesthetic, and that each case had to be determined as regards its anaesthetic risk on its own merits.

In the afternoon Dr. E. I. McKesson exhibited his new apparatus for the induction and maintenance of nitrous oxide and oxygen gas anaesthesia. Dr. S. R. Wilson followed with a paper in lighter vein on the evolution of anaesthesia, in which he humorously recounted the progress of anaesthesia from Helen of Troy—whom he claimed as the first anaesthetist on record—to the present day, as exemplified in the wonderful apparatus which had just been exhibited. Lantern slides, in which pictures of Helen of Troy and of the succeeding generations of anaesthetists figured, added much to the interest of a lecture delivered in Dr. Wilson's best and most humorous vein.

Before the meeting was dissolved Dr. Rawlings gave a demonstration of some new apparatus he had devised for the safe administration of chloroform as an adjunct to anaesthesia with ether, as he considered ether undesirable in cases of long duration when used by itself. The meeting then dissolved after a hard day's work which had proved interesting and profitable.

## SECTIONS OF ANAESTHETICS AND SURGERY.

Friday, July 23rd.

### ANAESTHESIA IN ABDOMINAL SURGERY.

At the joint meeting of the Section of Anaesthetics and the Section of Surgery Dr. Samuel Johnston, President of the Anaesthetics Section, was in the chair, and a discussion on anaesthesia in abdominal surgery was opened by Professor Finsterer (Vienna) with a paper on splanchnic anaesthesia for gastric surgery. Mr. C. W. Moots (Toledo) followed with a paper entitled "The evaluation of the risk; blood pressure protection, and nitrous oxide anaesthesia as vital factors in gastric surgery." Dr. C. Langton Hewer (London) dealt with endotracheal administration of nitrous oxide-oxygen-ether in gastric surgery; and, in the absence of Dr. Ian MacDonald (Spain), his paper on intravenous somnifene anaesthesia was read by a deputy. An interesting discussion followed in which both surgeons and anaesthetists participated. The meeting seemed to be divided into two main camps. In one group were those who deemed it fit that there should be co-operation and consultation between the anaesthetist and the surgeon before operation, to determine the operative risk and the choice of anaesthetic. The other group included one speaker who thought that the anaesthetist should do as he was told by the surgeon: since the case was the surgeon's he had the right to dictate the choice of anaesthetic as well as the appropriate preparation of the patient. The "team work" fetish was being worshipped excessively and a check on this extravagance should be imposed. The majority of the surgeons were, however, in favour of close co-operation between surgeon and anaesthetist, and the anaesthetists were overwhelmingly in favour of this course. Individual surgeons and anaesthetists preferred to use the routine methods to which they were accustomed in ordinary cases, though in special cases they were quite willing to make trial of the less familiar methods. The fact emerged that there was no perfect anaesthetic yet in use, each and every one having disadvantages to counterbalance such advantages as it possessed. Ether, like chloroform in former times, was passing through a period of unpopularity with the risk of being ousted from its place as the chief stand-by of the anaesthetist. It was concluded that it would be long, however, before either ether or chloroform would cease to be used by the occasional anaesthetist, who could not afford the expense of a motor lorry and a gang of porters to provide transport between the scattered homes and houses in which he worked for the weighty apparatus necessitated by modern gaseous methods for the administration of anaesthetic vapours. For those professional anaesthetists who worked in well equipped institutions the matter was different, since the problem of transport did not arise with such urgency as in the case of the occasional anaesthetist.

## SECTION OF PATHOLOGY AND BACTERIOLOGY.

Thursday, July 22nd.

PROFESSOR J. SHOLTO DOUGLAS paid a warm tribute to Sir William Leishman, who should have been with them that day. Sir William's memory would be cherished by pathologists through the ages, both for his kindly personality and for the great work he had done for pathology, and, through pathology, for his country.

### RELATION OF STREPTOCOCCI TO SCARLET FEVER AND ITS COMPLICATIONS.

Dr. R. A. O'Brien summarized the characters of the *Streptococcus scarlatinae*, and the reason for believing that it was the cause of scarlet fever. Three important questions remained for discussion. Could it be decided quickly and certainly whether a given haemolytic streptococcus of unknown origin was *S. scarlatinae* or not? Were there different types of scarlet fever caused by different strains of streptococcus? Did *S. scarlatinae* attack only as a toxic organism, or also by the septic or pyrogenic method? In answer to the first question the speaker said that *S. scarlatinae* could not be quickly and certainly identified because, although the group was fairly well defined serologically, occasional strains failed to agglutinate with the specific scarlet fever serum, while some haemolytic streptococci from other diseases did so. With regard to the second question, subgroups existed, but their biological significance could not at present be determined. Evidence based on the Schultz-Charlton test seemed to show that all strains were toxigenically identical. The relation of puerperal and surgical to ordinary scarlet fever was not clear. As for the third question, the toxigenic factor appeared to be the most important clinically, since the beneficent action of antitoxin, when given early in the disease, approached that of the specific antitoxin used in the treatment of diphtheria. In experimental animals, however, septicaemia was an important factor.

Dr. C. C. Okell gave an account of some of the difficulties met with in titrating scarlet fever toxin and antitoxin. The difficulties of finding the neutralizing power of an antitoxin in terms of a known toxin were even greater. At present no close quantitative comparisons of serums were possible, although the therapeutic effect might be gauged to some extent by toxin neutralization tests, blanching tests, or the passive immunity method. He then discussed the toxic and the pyrogenic role of the streptococcus in scarlet fever and the therapeutic results of the antitoxin.

Dr. K. E. Birkhaug gave the results of very extensive researches into the bacteriology of the mouth and ears in cases of scarlet fever, and spoke of his experiences of the carrier problem. His study of the mechanism involved in the production of the scarlatinal rash and its neutralization by means of antitoxin had produced some interesting results. He used Krogh's method of direct examination of skin capillaries in this work with signal success. His experience with specific therapy confirmed that of other workers. Dr. Birkhaug also read a paper on the etiology of erysipelas and its specific therapy. After giving an account of his studies of the *Streptococcus erysipellatis*, he showed the results of treatment with specific serum in a most interesting series of cases.

## SECTION OF DISEASES OF CHILDREN.

Wednesday, July 21st.

### ACUTE NEPHRITIS IN CHILDHOOD.

At the beginning of the meeting the President, Dr. Thursfield, alluded to the great loss sustained in the field of medicine associated with diseases of children by the death of Dr. John Thomson. Dr. Leonard G. Parsons, opening the discussion on acute nephritis in childhood, said that although the problems of nephritis in the child were relatively simpler than in the adult, "simple" was the last word that could be applied to them, as many seemed at the moment to be insoluble. He divided cases into the haemorrhagic and the hydraemic groups. The haemorrhagic group was the larger; it often occurred after

tonsillitis, there was little oedema, albuminuria was less than in the other group, oliguria was frequently absent, and most of the patients tended to recover. In the hydraemic group there was often no previous disease, oedema was marked, there was more albuminuria, less urine, many casts and pus cells, and the patients showed more tendency to become chronic cases. To these groups might be added a febrile group connected with acute infections—diphtheria, scarlet fever, pneumonia, or rheumatism. Dr. Parsons then discussed the various theories of the respective parts taken by the glomeruli and the tubules in nephritis, and thought it justifiable to assume that the defect in oedematous cases was in the tubules; while in haemorrhagic cases the blood originated from the glomeruli. On the other hand, this view had recently been criticized by Mayr. From the pathological point of view haemorrhagic cases could be divided into focal and diffuse glomerulitis, and exudative or tubular cases into mild and severe which often passed on into a subacute form—nephrosis. A third group of mixed, diffuse glomerulo-tubular nephritis often went on to chronic parenchymatous nephritis, and in later life to secondary contracted kidney. Nitrogen retention, raised blood pressure, and uraemia might be seen in either of the main groups of cases, and were dependent upon the severity of the attack. A "critical diuresis," coming on a few days after an early oliguria, was of great prognostic importance. When it occurred after a short oliguria the patients very commonly recovered. If the tubular cells were only damaged and not necrosed, it would appear that they remained active enough to resist the absorption of urea, although possibly unable to resist absorption of threshold bodies. As regards etiology, Dr. Parsons said that the exudative type of nephritis often arose without any obvious cause, while the haemorrhagic type was often associated with acute infections, especially streptococcal. Some had thought that the exudative type was due to nasal sinusitis. Prognosis in the disease was complicated by the difficulty in deciding whether a patient had recovered or not. Mild cases in both groups recovered, but exudative cases tended to become chronic. At the same time functional recovery appeared to occur in some subacute or chronic cases, after all hope of a favourable termination had been abandoned. In treatment the important matters were rest, a suitable diet, and the removal of any focus of septic infection. The patient should remain in bed at least three months, and the food should be at first milk, with sugar, barley-sugar, and fruit juice. As soon as possible attention should be paid to the tonsils, teeth, and skin infections. Diuretics, even if not harmful, were useless.

In the discussion which followed Dr. Parsons's paper, Dr. J. M. Smellie referred to the divergence of opinion in classification and prognosis. He described some investigations he had made, based on a division into early, intermediate, and late prognosis. He thought that if the original acute disease received efficient treatment, complete recovery would occur in many cases. Inadequate treatment of the initial acute infection was largely the cause of subacute or chronic nephritis in early adult life. Drs. Spence, Barber, Tuke Ashby, Wilkie Scott, and others took part in the discussion.

Dr. E. H. M. Milligan then read a paper on goitre in childhood, based on the investigation by the Ministry of Health, and appealed for the assistance of general practitioners in investigations of this kind. He produced figures showing the remarkable variation in the incidence of the disease among children in various parts of the country. He mentioned the association with goitre of such conditions as nose and throat trouble, rheumatism, and mental deficiency, and described the types and causes of the disease. He stated that at Glossop a scheme of treatment had been undertaken by the public health authority, by the administration of iodine, often in chocolates, to school children suffering from enlargement of the thyroid. The surprising differences in incidence described by Dr. Milligan were criticized by several of those present; and the use of iodized salt was suggested as the simplest, cheapest, and most effective method of treatment.

In the afternoon a visit was paid to the Children's

Hospital, now being enlarged through the munificence of Mr. J. D. Player. An extremely interesting series of cases was shown by Dr. Wilkie Scott.

## SECTION OF ORTHOPAEDICS.

Friday, July 23rd.

### NON-TUBERCULOUS COXITIS IN THE YOUNG.

MR. H. A. T. FAIRBANK, opening a discussion on non-tuberculous coxitis in the young, said that coxitis arose from either trauma or infection. Recovery followed traumatic synovitis in the absence of immobilization. Epiphyseal strain was the first stage of adolescent coxa vara. Some such cases with muscle spasm might be taken for tubercle. All types of infective arthritis might be caused by the same organism of varying virulence. In a subacute type the pneumococcus might be suspected. Acute osteomyelitis with secondary arthritis presented difficulties of diagnosis, and pseudo-coxalgia might be simulated by tubercle. In dislocation of the hip traumatic arthritis might follow reduction. Osteo-arthritis occurred chiefly in subluxated hips. Arthritis deformans juvenilis was very rare as a primary affection; it was preceded by anatomical abnormality. Mr. S. W. Daw said that there were a number of anomalous cases which would not yet fit into any classification. He referred to the difficulties of diagnosis in the early stages of rheumatoid arthritis (Still's disease), and added that the distinction between pseudo-coxalgia and tubercle was sometimes difficult. Many patients with unreduced congenital dislocations of the hip reached middle life without suffering pain or great disability. Dr. S. T. Irwin drew attention to the importance of the bar of cartilage which existed up to the age of about 11 between the capitular cartilage and the neck of the femur. This he believed prevented slipping of the epiphysis, which was rare before that age. He exhibited some very beautiful preparations of infantile femurs illustrating this point, and also a number of lantern slides illustrating displacement of the femoral epiphysis. Mr. T. P. McMurray pleaded for simplification of classification into tuberculous and non-tuberculous, dividing the latter into traumatic and infective. This would include all except pseudo-coxalgia, which much resembled Köhler's disease of the tarsal scaphoid. Both might be congenital. Mr. Harry Platt emphasized the importance of the age of the patient in the formation of a differential diagnosis. He mentioned the importance of recognizing the presence of extra-articular tubercle of the neck of the femur and treating it early. A valuable symptom of acetabular disease, much relied on in France, was enlargement of the iliac glands on the affected side. Mr. Alan Todd advocated elaborate clinical classification as a means of increasing our knowledge of the real varieties. Juxta-epiphyseal strain was, he was sure, a real stage of coxa vara. Gonorrhoea was a cause of arthritis in young children who suffered from vulvo-vaginitis. Histological examination of the blood might be a means of diagnosis between tuberculous and non-tuberculous arthritis. Early diagnosis and treatment of congenital dislocation of the hip was important, for while a few unreduced cases might do well, many did not. Mr. F. C. Pybus said that there was extensive vascularization of the epiphyseal cartilages before ossification, and that thus primary vascular infection of the hip might occur. He thought that in chronic tuberculous joints some movement might be allowed cautiously as was done by Rollier. X-ray evidence of pseudo-coxalgia might appear before or after the detection of clinical evidence. This disease might be associated with coxa plana. When tubercle of the neck of the femur was detected early operation was demanded before the joint became involved. The classification should be as simple as possible. Mr. W. A. Cochrane thought that the angle of the plane of the epiphyseal line between the head and neck of the femur more or less predisposed to slipping of the head as it was more or less vertical. Acute infection of the joint needed opening and free drainage.

On the afternoon of Thursday, July 22nd, Mr. S. Alan S. Malkin and Mr. Frederick Crooks showed a number of

interesting cases to the members of the Section at the clinic of the Nottingham District Cripples' Guild. The results obtained in the completed cases were excellent, and some of the patients awaiting treatment presented interesting problems of diagnosis and treatment.

### SECTION OF MEDICAL SOCIOLOGY.

*Friday, July 23rd.*

#### THE PHYSICAL AND MENTAL EFFECTS OF FATIGUE AND MONOTONY IN MODERN INDUSTRIAL WORK.

##### *Morning Session: The Monotony Factor.*

In opening the morning session of the Section of Medical Sociology the President, Mr. C. J. Bond, drew attention to two principles to be remembered in laying a solid biological foundation for a system of industrial psychology and physiology: first, that every human being strives to obtain a sense of satisfaction from work done; secondly, that the industrial problem is an evolutionary one of adaptation to the industrial environment. Two things, therefore, were needed: to make industrial toil more satisfying to the mind, and to fit the work to the worker and the worker to his work. Mr. A. Hudson Davis of the National Institute of Industrial Psychology opened the morning discussion on the monotony factor. He found difficulty in separating monotony from fatigue; the former was really a special phase of the latter. Monotony was not an objective characteristic of work. In one sense there was no such thing as a monotonous job. Monotony was the reaction of certain human beings to certain jobs under certain conditions; and the job need not necessarily be repetitive. The mental results of monotony might be inertia and lack of interest, and discontent leading, through atmosphere of disaffection and unrest in the workshop. Physical results were not direct and obvious, though symptoms sometimes occurred of functional defence reactions, such as miner's nystagmus. The physical results were chiefly visible in fall of output, a drop below maximum efficiency, variability in the rate of working, and unorganized protective rests from exertion. In removing monotony a balance must be kept between too much change, which had an irritating effect, and too little change with its danger of monotony. Interest in the work must be increased, together with *esprit de corps*; and shop organization should be good. The value of rest pauses was marked; but some change of work, if possible, was even more desirable than rest. Any source of irritation in environment should be removed. Mr. Hudson Davis concluded with some remarks on vocational selection and tests. He was of opinion that those who suffered from monotony were mainly the badly adapted and the intelligent, though intelligence often worked towards the overcoming of monotony. Miss May Smith of the Industrial Fatigue Research Board had found that the highly educated more commonly complained of monotony, but that repetitive movements were not necessarily monotonous. The investigator too often put himself in the place of the worker, and judged the work on what he thought would be the result if he himself were doing it. Miss Smith discussed at some length the relief to monotony afforded by day-dreams. Major T. Knowles, supervisor of Messrs. Boots' Welfare Centre, criticized the use of such expressions as "monotony" and "self-development." He showed that repetitive work was not necessarily monotonous; that repetitive work was essential to production; that many mental stimuli lessened the monotony of repetitive work; and he regarded leisure as the time for self-development. In one of the office departments he had found that the incidence of sickness among girls employed in ordinary office work was twice that of girls employed in repetitive work. Major Knowles hinted that constant suggestion that repetitive work was injurious might arouse artificial discontent. At the same time every effort must be made by employers to secure the welfare of their workers. Miss Slocock, superintending inspector of factories, emphasized the necessity of getting at the worker's view. Character and temperament played so large a part that what appeared monotonous to one person would not be so in the least to another. She thought that

the absence of a creative aspect in work caused the sensation of monotony. Miss K. Dowding of the Chiswick Polish Company urged the careful selection and placing of workers. One discontented worker would make a job unpleasant for a whole body of workers; suggestion was contagious. Sir Thomas Legge desired to see comity between employers and employed, such as existed in the days of mediæval guilds. He thought that competition was leading to monotony; but he had not noticed much complaint of monotony from the workers themselves. He looked to co-operation between employers, trade unions, and welfare workers to bring back some portion of interest in work. Drs. Stewart Mackintosh, Robb, Lockhart, Christine Murrell, C. Forbes, Brackenbury, and Beadles took part in the discussion; and Professor Winifred Cullis submitted a paper which she was unable to be present to read.

##### *Afternoon Session: The Physical Fatigue Factor.*

Mr. W. L. Hichens, chairman of Cammell, Laird and Co., read a paper on industrial physical fatigue. He thought that the introduction of the word "fatigue" into the name of the Industrial Fatigue Research Board was unfortunate. It suggested too much and too little. It suggested that fatigue prejudicial to the health of workers existed; whereas at present there was no such condition in any industry in this country. It did not suggest that some industries involved much more fatigue than others, and that in these the point at which fatigue began should be postponed. Research work should be directed to the elimination of all unnecessary physical labour by means of machinery. Time-motion study should be carried out, as well as researches into the design of machinery. In these studies Mr. Hichens thought that they had done at least as much on the theoretical side as had been done in America; but it was of prime importance to enlist the interest of the workers in improvements. Local fatigue was the most important and insidious form of fatigue. The effect of temperature should be studied, output being less in hot weather than in cool. Mr. Hichens regretted that hours of labour were a subject of political controversy rather than scientific study. Further subjects for research were the incidence of sickness, the lighting of factories, baths, liability of accidents, and vocational selection and guidance. Dr. H. M. Vernon read a paper on the effects of temperature and ventilation in lessening fatigue in various occupations, and illustrated his remarks with lantern slides. He stated that the effects of fatigue on health were more difficult to estimate than the effects on efficiency. There was an increase of accidents with increase of hours; but accidents also increased with rise of temperature. Dr. Stewart Mackintosh and Mr. C. J. Bond took part in the discussion. Professor Leonard Hill and Mr. F. Varley, M.P., were unfortunately prevented from being present to read their papers.

### SECTION OF DERMATOLOGY.

*Friday, July 23rd.*

#### ECZEMA.

Dr. ARTHUR WHITFIELD said that eczema was the most important thing in the whole of dermatology on anatomical and physiological grounds. The essential feature of it was a special or general irritability of the skin—a susceptibility of the patient—which enabled exposure to various external agencies to call forth the eruption, when a normal individual would be unaffected. The constitutional factor was of great importance, and could be best explained by postulating the existence of a type of toxin which acted on the epidermo-papillary system so that the slightest possible trauma excited an eczematous reaction. He explained those cases in which mental anxiety or shock seemed to cause an attack by supposing that digestive disturbance resulted in an erroneous chemical cleavage of the food with the production of an alimentary poison. He preferred not to use the term "seborrhoeic eczema," but to employ the term "pityriasis capitis" for the dry scurfy head, its simplest form, and to agree with Sabouraud that it was due to infection with the *bottle bacillus*. Superimposed on this infection there might

also be infection with the non-liquefying staphylococcus, which on the body gave rise to reddish rings, which the speaker considered as only a low-grade bacterial infection. On the other hand, he did desire to recognize as a form of eczema an eruption of V-shaped distribution over the shoulders and upper back where the lesion was a discrete spongy papule, microscopically indistinguishable from the lesion of simple eczema, except that the lesion was localized rather specially at the mouth of the sweat gland; he believed this form to be a true eczema of chemical origin caused by bacterial decomposition of the sweat.

Dr. Dyson suggested that the epithelium of the skin was a secretory organ and that some day it would be found to act as a ductless gland. Dr. Barber classified different types of eczema from their clinical appearances. Eczematous lesions might occur in seborrhoeic patients, and focal sepsis was important in many cases. One patient had been cured by evacuation of pus from the antrum, another after removal of intestinal indican by the Plombières treatment, and another after the extraction of a septic tooth. Dr. Hallam doubted whether external irritation was absolutely necessary for the production of eczema. He thought that sometimes the external irritant might be replaced by an internal irritant distributed by the blood stream. Dr. Haldin-Davis said that in many cases there was either hyperglycaemia or sugar intolerance. He thought that the symmetrical distribution of the lesions was determined by spread through the nervous system. Dr. H. C. G. Semon said that there must be some "tissue idiosyncrasy" of the skin, and that eczema never occurred on a naevus, possibly because the skin over such an area was always devoid of vaso-constrictor nerves. Sir Norman Walker recalled that he had been present at the British Medical Association meeting at Nottingham in 1892, when the Dermatological Section had not been started. In those days the fashionable cause of eczema was gout; nothing was ever heard of it now as a cause of eczema. He was convinced of the importance of focal sepsis and of treating scurf of the scalp. The President said that there must be an oedematous base to the eczematous vesicle. He distinguished between traumatic dermatitis and eczema; the former was much more superficial than, although it might ultimately develop into, eczema.

#### TREATMENT OF PSORIASIS.

Dr. R. W. MacKenna, in opening the discussion on psoriasis, deprecated the use of strong applications in acute attacks, in which he found antimonial wine very useful, with, locally, an oily calamine lotion. He discussed the employment of emetine, arsenic, salvarsan, auto-haemotherapy, and vaccines of various kinds; four out of sixteen cases improved on a course of vaccines made by the Danysz method. Better results had been obtained by producing "fixation abscesses" with the aid of terpinchin injected in doses of 1 c.cm. weekly into the gluteal region. Seven out of fourteen patients showed distinct improvement after the first injection, and it was certainly helpful to any local treatment also employed. He had treated fifteen cases with intramino, and had found it distinctly beneficial in all except one. He was most favourably impressed with x rays and ultra-violet light: x rays for the removal of lesions from special areas such as the face, neck, and hands; ultra-violet light for general irradiation. He found it useful in all stages of the disease, and had had some excellent results from it. He advised strict moderation both in food and in tobacco and the interdiction of alcohol. He thought that the return of the eruption was delayed longer after tar than after chrysarobin treatment. Salicin was of undoubted value internally in some cases; sulphur, salicylic acid, mercury, and pyrogallol acid all had their sphere of utility.

Dr. Dyson emphasized the importance of rest; he had found salicin and arsenic the most useful drugs. Tar had a drawback in that it caused troublesome furunculosis, and x rays he had discontinued altogether. He had found vaccines useful as an intermediate treatment for the prevention of attacks. Dr. Barber said that ultra-violet light did more harm than good; at times it caused generalized spread of the disease. He advocated conservative action by British dermatologists to ascertain the cause of

psoriasis. He and Dr. Embleton had isolated an organism which, when made into a vaccine, had always made the patient worse; he thought this was suggestive. Dr. Skinner described a series of cases which demonstrated the superiority of chrysarobin over x rays as a method of treatment. He also showed some sections illustrating the pathology of the disease. Sir Norman Walker had found arsenic occasionally very useful in acute cases. He said he was less pessimistic than others about the chance of recurrence of the eruption, and that he had had several cases which had remained free for many years. Dr. Whitfield advocated the use of creosote internally in psoriasis, and Dr. MacKenna replied.

#### SECTION OF OPHTHALMOLOGY.

Thursday, July 22nd.

##### RETINAL HAEMORRHAGE.

At the first morning session the chair was taken by Mr. Elmore Brewerton (Vice-President of the Section). The proceedings opened with a demonstration of operations for glaucoma simplex by Dr. George Young (Colchester). He made two small trephine holes on the scleral side of the limbus at the lower part of the cornea, then removed the fibres of the ciliary muscle to reach the uvea. The discussion for the day, on the significance of retinal haemorrhages, was opened by a paper by Mr. R. Foster Moore, which in his absence was read by Dr. A. Christie Reid. He commented upon the importance of the experimental work done by Ricker and Regendanz on the conjunctiva of rabbits, in one of which the conjunctiva was severely irritated by finely powdered pumice-stone, which was then washed out. There was immediate strong hyperaemia, and in a few minutes complete stasis. In the second experiment a solution of abrine was dropped into the conjunctival sac. There was no immediate effect, but eight hours later there was pronounced hyperaemia, and next day the vessels were much dilated. There was marked capillary stasis and capillary haemorrhages, which increased for several days. The haemorrhages seemed to be due to poisoning of the endothelial cells by the abrine; and in poisoned states of the blood, such as diabetes and renal disease, retinal haemorrhages were of frequent occurrence. Thus it seemed evident that certain poisons especially affected capillary walls, so that they no longer maintained an inviolate barrier against the passage of cells from within their lumen. It seemed that the picture presented was that of an endothelial cell or cells whose health was impaired by the action of a toxin, to the extent that the endothelial tube was no longer inviolate, but that a defect in it developed sufficiently gross to allow of the escape of the cellular elements of the blood into the tissues, through a stoma from the opening up of the line of junction of separate cells or from a breakdown in the cell itself. The toxins of certain organisms appeared specially to lead to haemorrhages. He did not believe that retinal haemorrhages of arterio-sclerosis were caused by an increase of pressure in the arteries or capillaries; they occurred only in somewhat advanced cases, and suggested that the haemorrhage was an expression of the defective circulation through the vessels, so that the nutrition of their endothelium was impaired and consequently a leakage of blood occurred. Haemorrhages, no matter how profuse or large, produced no permanent change in the retina unless the external limiting membrane was lacerated. Dr. C. O. Hawthorne agreed that damage to tissues preceded retinal haemorrhages, and not mere changes in blood pressure. He would say that the cause was undue fragility of the vessels. Retinal haemorrhages might appear as the first and only sign of severe constitutional disease, so that no safe diagnosis could be made without ophthalmoscopic examination, and that not once but several times. The paper was discussed also by Mr. G. H. Pooley (Sheffield), Mr. M. L. Hine, Mr. T. Harrison Butler (Birmingham), Mr. Bishop Harman, and Dr. Peter Macdonald (York).

Mr. Bishop Harman (London) read a paper on the Chorley Wood College for the higher education of girls with little or no sight. He pointed out that in 1917 the Interdepartmental Committee on the Welfare of the Blind reported that there was urgent need for a college for blind

girls. In 1921 this need had been met by the establishment of a splendid college for girls at Chorley Wood, Herts. He gave an account of the work of the college, and showed that at a visitation by medical and educational experts from the Board of Education in 1925 the whole work of the college had received the highest praise. It was now the duty, he considered, of all ophthalmic surgeons who had blind girl patients of their own class to secure that the knowledge of this college should be brought to the parents of such children; no better thing could be done for them than the introduction to a public school education.

At the afternoon session Mr. Basil Graves (Liverpool) performed the operation devised by Dr. Wheeler of New York for capsulotomy. A fine knife was entered through the cornea from above with its edge directed downwards, the point was made to reach the capsule below the iris border at its lower segment, then with a quick backward and upward movement the knife was withdrawn, severing the capsule from below upwards and without loss of aqueous. Mr. G. H. Pooley (Sheffield) demonstrated his operation for chronic dacryocystitis. A small skin incision gave access to the sac, which was severed from below the tenon oculi down to the site of the lacrimal duct. Then the bone at the mouth of the ducts was cut away with a sharp gouge and mallet, the fragments were removed with a scoop, and finally the passage packed with a faggot-like bundle of catgut, and the skin opening closed. Dr. George Young (Colchester) read a paper on the cause of stammy cornea in glaucoma, which he suggested might be due to an optical effect produced by the slipping of the corneal layers under tension. Dr. Arnold Verrey (Lausanne) read a paper on Nagel's anomaloscope for defects of colour vision. In a suitable instrument, like a telescope, there was placed in one half of the field a yellow filter screen, the other half was fitted with a red and green filter, which could be mixed at will by suitable gearing until a yellow colour matching the yellow screen was obtained. The accuracy of the match was a test for colour vision, the defects could be measured accurately by the position of the gearing. Mr. Harrison Butler read a paper on slit-lamp results by simplified methods. By the use of the half-watt electric lamp a linear illumination of the front of the eye could be made without elaborate projectors, and the tissues in this linear illumination could be magnified by a powerful corneal loupe, so that many of the finest effects of slit-lamp methods could be obtained with comparative ease.

## SECTION OF PUBLIC HEALTH.

Wednesday, July 21st.

### POOR LAW REFORM AND PUBLIC HEALTH.

Dr. P. BOBBYER, who presided, opened with a short comparison of the present health conditions of Nottingham with those in 1882, when the Association last met there. The general death rate, which was then 18 per 1,000, had fallen to 12, and the infantile death rate had been reduced from 200 to 85. Enteric fever then, and for five years afterwards, used to average over 400 cases annually, and in one year there were 617 cases with 114 deaths. Deaths from infantile diarrhoea averaged 335 per annum. Both these diseases had now been practically eliminated with the disappearance of 40,000 pail closets. Dr. J. Middleton Martin, opening the discussion on reform of the Poor Law, mentioned that whereas in 1851 5.3 per cent. of the population were paupers, there were in 1921 only 1.75 per cent. The subsequent increase was due to industrial conditions and might be regarded as temporary. Various modern public health services had taken over some of the functions of the Poor Law. Disease was being increasingly recognized as a cause of pauperism, and illness was preventable by improvement of social conditions. The speaker thought that the duties of district Poor Law medical officers should be shared among all medical men practising in the district on lines similar to those of the National Insurance Act. Dr. R. P. Garrow said that Poor Law reform had been made an excuse for placing non-county boroughs and urban districts under the control of the counties, and that the proposals in the Memorandum of the Ministry of Health were viewed with consternation by the

members and officials of such authorities. Dr. A. L. Baly thought that the Poor Law was often blamed for the faults of its administrators; it was not generally realized how much could be effected under the Poor Law when it was well administered. The acceptance of any public service which was not paid for in full should involve the local disfranchisement of the recipient. Dr. E. Hill held that the Memorandum of the British Medical Association ignored the necessity for the unification of medical services which was the essence of the proposals of the Minister of Health. Dr. D. C. Kirkhope was of opinion that health administration should follow the line of concentration on the individual; this could only be done by the medical officer of a smaller area with his more intimate knowledge of its population. Dr. Stella Churchill said that existing methods in London caused a great deal of overlapping. She could not agree with the suggestion of disfranchisement, since many municipal services, such as hospital provision for infectious cases and child welfare centres, were accepted without payment. Dr. G. H. Pearce gave several instances of the difficulties that would arise in boroughs and urban districts placed under the control of the county council. Dr. H. Scurfield said that any satisfactory scheme for the unification of services must include the formation of areas large enough to employ whole-time medical officers. Dr. B. Hill approved the retention by combined districts of all the public health duties at present allotted to them, in order to preserve the individual touch in public health work. Professor F. E. Wynne thought the differences of opinion were more apparent than real. Nobody wanted to rob a large and highly equipped borough of its health functions, but there were rural districts in which neither the county nor the local authority exercised any real control over sanitation. Dr. H. B. Brackenbury further explained the Memorandum of the Association, which, he said, contained only the considered policy of the Association as adopted from time to time by the Representative Meeting and the Council. Dr. Middleton Martin, in his reply, said he had never suggested any want of competence in Poor Law authorities. Nor did he state that the counties must necessarily be the sanitary authorities in future. Some form of unification was necessary, and in many cases, he thought, the county would prove to be the best administrative unit.

The second day's discussion, on food deficiency, is reported in full at page 185.

## Reviews.

### OPERATIONS ON THE SYMPATHETIC NERVES.

UNDER the title of *Chirurgie du Tonus Musculaire*,<sup>1</sup> Dr. P. WERTHEIMER of Lyon and Dr. A. BONNIOT of Grenoble have published their observations on the results of surgical division of the grey rami communicantes in the cervical, thoracic, and lumbar regions. The whole subject is reviewed critically from the anatomical, physiological, and surgical standpoints, and finally the results of eighty-nine operations on the sympathetic which they have themselves performed are analysed.

After a careful description of the anatomy of the sympathetic ganglia and nerves, based chiefly on the researches of Professors Leriche and Hovelacque, the authors proceed to a review of the relation of the sympathetic system to muscular tone. They trace the development of the researches of Brondgeest, de Boer, Boeke, Sherrington, Langelaan, and others on the apparently dual nature of muscular tone, plastic and contractile, and the histological evidence produced by Perroncito of two kinds of nerve fibres, myelinated and non-myelinated, distributed to striped muscles. Finally they discuss the work of Hunter and Royle, which forms the basis of the indications for surgical treatment: interwoven with this is the histological work of Kulchitsky, to which, however, they do not specifically refer. After a passing reference to the operation of posterior root section as performed by Foerster for the relief of spastic conditions, and the opera-

<sup>1</sup> *Chirurgie du Tonus Musculaire*. Par P. Wertheimer et A. Bonniot. Paris: Masson et Cie. 1926. (Roy. 8vo, pp. 136; 21 figures 22 fr.)

tion of Leriche of periarterial sympathectomy in certain vascular lesions, they describe in detail the technique of section of the sympathetic rami in the different regions with the object of reducing excessive "plastic tone." Cervical ramisection is performed under local anaesthesia, lumbar ramisection with root anaesthesia. In their eighty-nine operations there was no death, and they lay stress on the absence of any serious complications and the general safety of the operations. Their results are on the whole much more encouraging than those which have been obtained by surgeons in this country, judging by the opinions expressed at a recent discussion of this subject by the Section of Neurology of the Royal Society of Medicine.

Their best results followed in cases of infantile cerebral palsies and in cases of spastic contracture following cortical disease or injury; in vascular lesions of the pyramidal tracts and in sclerotic lesions of the cord the effects were less encouraging. They also obtained striking results in some cases of the "reflex contractures" of Babinski following peripheral injuries, the "reflex" nature of which has been contested by Hurst and others. They have not made any observations on the effect of the operations on cases of the Parkinson syndrome. In general the effects produced were increased freedom of movement in the operated limb or limbs, diminution of the hyperactivity of the tendon reflexes, and increased passive movement, with consequent improvement in voluntary control.

The authors are careful to make no excessive claims for this new branch of surgery, but their book, which is well illustrated and has an introductory chapter from the pen of Professor Leriche, is of much value as a clear presentation of the present position.

#### THE NOSE AND ACCESSORY SINUSES.

THE fifth edition of the book on the pathology and treatment of inflammatory affections of the accessory sinuses of the nose,<sup>2</sup> by Professor HAJEK of Vienna, is welcome, if only because twelve years have elapsed since the last edition was published; the first dates back to 1898. The author therefore has not only introduced later researches on pathological anatomy, but from his own large experience has been able to lay down with more precision the indications for conservative methods of treatment in some circumstances, and to say why it is that only radical procedures can succeed in others. For those who intend to undertake operations on the accessory sinuses and hope to do so not only with safety to the patient but also with success, an intensive study of the anatomy of the nose is essential. In this Professor Hajek is a safe guide, and in so far as it can be learnt from books the numerous anatomical illustrations are in themselves an education; in addition a number of finely executed representations of the microscopic structure of diseased tissues have been introduced into this edition. Operative treatment of all kinds is fully described, and an account is given of Krönlein's operation, which may be employed in some retrobulbar inflammatory conditions, though usually reserved for the exposure of new growths.

It is, however, to the study of pathological anatomy that Professor Hajek particularly devotes himself, a study which he rightly considers provides the safest path to the solution of the innumerable problems which arise. The description of mucocoeles from this point of view is particularly enlightening, and it is interesting to note that mucocoele of the sphenoidal sinus is described, for its existence has sometimes been questioned, no doubt on account of its rarity. Professor Hajek himself points out that the study of the inflammatory disorders of the accessory sinuses in connexion with rhinology dates back for at least twenty-five years, so that it was not to be expected that anything very new or startling should be found in this edition; but it is gratifying that in spite of the unfavourable times this volume, so full of mature wisdom and so admirably produced, has issued from the Vienna school.

#### PERITONEAL ADHESIONS.

THE etiology and significance of peritoneal adhesions have received a good deal of study on the part of surgeons and pathologists in recent years, and at all times their importance has been recognized in connexion with diseases of certain organs, such as the stomach and appendix. But for the most part the peritoneal lesion has been regarded as an accompaniment or sequela of some definite visceral disease, constituting merely a stago in the latter and not an independent pathological entity. It is now known, however, that apart from visceral disease peritoneal adhesions and thickenings may be produced under the influence of purely mechanical or developmental conditions, and, moreover, even when resulting from visceral disease, may persist after the disease of the organ has healed and assume the characters of an independent affection. It would seem, therefore, that the time has arrived when these peritoneal conditions may be profitably considered independently and as a whole, with their diverse clinical manifestations dependent on the modifications in form and function which they produce in related organs. This task has been undertaken in a series of lectures forming part of a course of gastro-enterology given under the direction of Professor CARNOT at the Beaujon Hospital, and published under the title of *Les Périviscrites Digestives*.<sup>1</sup>

The classification adopted is based on the organs affected by the peritoneal lesion. In connexion with the stomach descriptions are given successively of adhesions to the anterior abdominal wall and liver, to the hinder wall of the small omental sac affecting the pancreas or the solar plexus, and of adhesions involving the greater and lesser curvatures; and finally those affecting the pyloric and cardiac orifices. A second chapter treats of the various deformations of the duodenum which result from inflammations of the adjacent peritoneum; in the first place, those involving that part of the bowel which is situated above the attachment of the mesocolon are considered, and then those involving its lower segment. Of the former, separate consideration is given to the first part of the duodenum, to the curvature, and to the upper part of the descending portion. Of the latter, distinction is made between the lower half of the descending portion (related to infections of the ascending colon and appendix), the third part, and the duodeno-jejunal flexure. A third chapter deals with pericholecystitis in relation to its effects on the stomach, duodenum, transverse colon, and appendix; and a fourth with perityphlitis, periappendicitis, and pericolicitis of the ascending colon, including epiploitis, Jackson's membrane, Lane's mesenteric band, Reid's genito-mesenteric fold, and the parieto-colic fold of Jommesco. In a final chapter are considered the peritoneal inflammations affecting the descending colon and rectum—pericolicitis of the transverse and descending colon, the splenic flexure, perisigmoiditis, and perirectitis.

It will be seen from what has been said that the subject is treated in great detail, and it may be added that the clinical pictures of the various conditions described are excellent. Numerous reproductions are given of radiograms illustrating the deformities produced in the organs, and these are in most cases accompanied with explanatory diagrams, which are of great assistance, and indeed essential, to the uninitiated in radiography.

#### MEDICINE FOR THE MILLION.

IT is generally supposed that the lay public is thirsting for greater knowledge of health than heretofore, and that in the process it is prepared to learn more about disease and its treatment than has been vouchsafed to it by a jealous medical profession. For such inquirers Dr. G. T. WRENCH's book on *Domestic Medicine and Surgery*<sup>1</sup> will be of use. Dr. Wrench has adopted a different plan from that used in the ordinary dictionary of domestic medicine.

<sup>1</sup> *Les Périviscrites Digestives.* Par Paul Carnot, Blamontier, Libert, R. Friedel. Paris: J. B. Baillière et Fils. 1926. (Extra post 8vo, pp. 173; 67 figures. 1s. 8d.)  
<sup>2</sup> *A Textbook of Domestic Medicine and Surgery.* By G. T. Wrench, M.D., B.S. London: J. and A. Churchill. 1926. (Cr. 8vo, pp. vi + 339. 6s. net.)

to has grouped diseases, not alphabetically, but according to the symptoms as they appear to the patient and his friends. Thus we have, in the first place, the group of ebrile diseases, subdivided into sudden acute fevers, fevers of gradual onset without characteristic signs, and fevers of gradual onset with characteristic signs. The second group is distinguished by dominant symptoms, such as pallor or paralysis, either without fever or with fever of only minor importance. The third group contains diseases of special locality, such as the eye, ear, nose, or skin. Dr. Wrench's last group is accidents.

When a person is taken ill his friends, it seems to be suggested, should at once take his temperature. If this has been raised by sudden onset the friends should sit down and read Chapter II. They will find a choice of about a couple of dozen diseases, from pneumonia to sandfly fever, from sunstroke to acute osteomyelitis. Each disease is briefly and clearly described in language as non-technical as Dr. Wrench could make it; for he has tried to avoid the obscurantism in which he thinks all professions delight. With each disease there is a statement of the treatment usually adopted. It is anticipated that from a perusal of the book the patient's friends will avoid the twofold reproach of sending for the doctor unnecessarily or the more serious error of sending too late. Where, as in towns and in most parts of this country, a medical practitioner is not far off, most people will prefer sending for him in illness to the labour of symptom-hunting in a handbook. But we readily agree with Dr. Wrench that in remote corners of the widely scattered empire the knowledge he imparts will often be found useful. His little book is quite readable, even if not entirely free from technicalities. It is very complete, and the recommendations as to treatment are reasonable and within the understanding and capacity of the ordinary layman.

#### NOTES ON BOOKS.

DR. JEHANGIR J. CURSETJI points out, in his *Pocket Guide Book to Medical Life Assurance*<sup>5</sup>—by which he means medical examination for life assurance—that the examining physician should bear in mind the varying condition and vitality of different races in India due to climate, habits, and modes of life. He must have felt the difficulty himself, since he acknowledges that his book is mainly a condensation from various authors, probably European or American, and at the same time he sets forth the many differences in mortality returns of the various races living in India, which his various authors can hardly have had in mind. The book is a useful summary of the methods which should be adopted by medical examiners, and also indicates the conditions under which rejection of the proposer should be advised. Though the author thinks that the trend of opinion is in favour of the view that syphilis can be completely cured by early, careful, and prolonged treatment, he wisely does not recommend the acceptance even of a cured patient without loading.
